appeared normal. On section an area of subcortical softening was found in the left hemisphere near the midline, involving an area of 5 by 2 cm. This zone was brown and semifluid in consistence The basal ganglia appeared normal on both sides The cerebral arteries showed an extremely severe atheromatous degeneration with thickening of the vertebral and basilar arteries and of the two internal carotids The process was not calcific, and most of the thickening of the wall appeared to be due to yellow fatty material Even the smaller arterial branches were involved The heart weighed 440 Gm The coronary arteries showed considerable arteriosclerosis and tortuosity The main branches were patent On section of the myocardium, the left ventricle showed numerous foci of pale gray color, ranging in size up to 5 mm. in diameter There were narrow streaks of fibrosis throughout. Findings in other organs were not remarkable.

Discussion

Temporary spinal sympathetic block with reduction of blood pressure in the hypertensive patient has been found to be associated with persistence of vasoconstriction in the brain and significant decrease in cerebral blood flow [4] That similar response follows surgical sympathectomy is suggested by the observation that constriction of the retinal arterioles continues even after normotensive levels have been restored for long periods [5] The question arises, therefore, as to the advisability of "correcting" hypertension when there is impending failure of the cerebral circulation as a result of extensive arteriolar sclerosis Our studies in which high caudal block restored normal blood pressure levels for several hours in four hypertensive patients with recurrent encephalopathic episodes indicate that no improvement or an actual aggravation of symptoms accompanies this procedure when there is underlying cerebral vascular disease

These findings are in direct contrast with those of Jost who reported that he was able to prevent eclamptic seizures in each of nine patients with toxemia of pregnancy, merely by restoring normotensive levels through the use of caudal anesthesia [9] Obviously, the cerebral episodes in both conditions do not have the same pathogenesis Eclampsia is commonly associated with elevation of blood pressure, angiospastic cerebral phenomena, and edema of the brain Reduction in blood pressure with concomitant decrease in cerebral blood flow might, therefore, be expected to reverse cerebral changes in this condition Similarly, hypertensive encephalopathy associated with cerebral edema and/or angiospasm (without extensive arteriosclerosis) has apparently been benefited by surgical sympathectomy [7] In these conditions, reduction in blood flow to the brain, resulting from fall in blood pressure, would appear to be more than counterbalanced by the improvement in circulation arising from subsidence of cerebral edema and cessation of angiospasm.

In our cases, however, the same factors do not seem to have been operative No edema of the brain was found, as shown by the appearance of the eyegrounds, cerebrospinal fluid pressure, and autopsy studies Extensive cerebral arteriosclerosis with impaired cerebral circulation aggravated by angiospasm appeared responsible for the symptomatology Since the same clinical picture may occur with cerebral arteriosclerosis alone in the absence of arterial hypertension, the role played by the latter is not clearly defined [3] It is likely that elevation of blood pressure augments the tendency of diseased vessels and their collaterals to undergo spasm Consequently, although reduction in blood pressure may have lessened the degree of angiospasm in our cases, the concomitant decrease in cerebral blood flow in the presence of advanced arteriolar sclerosis apparently did not permit a favorable change in the impaired circulation of the brain. Indeed, it is theoretically possible, although not proved, that hypertension itself is occasionally initiated by cerebral vascular disease and when so evoked serves to maintain an adequate supply of blood to the brain That interference with such elevation of the blood pressure may actually precipitate clinical symptoms is shown by the observation of Fishberg, i e , that marked mental depression may follow surgical sympathectomy for hypertension in some cases [8] The writers, moreover, have witnessed the development of recurrent encephalopathic episodes in two hypertensive patients in whom elevated blood pressure was restored to normal levels as a result of acute coronary occlusion [10] It is significant that in neither of these patients was congestive failure or shock a part of the clinical picture Similarly, sudden fall in the blood pressure as a result of profound mercurial diuresis was found to have precipitated cerebral thrombosis in three elderly hypertensive patients with congestive heart failure [11] The possibility also exists that some of the cases, commonly regarded as cerebral embolism following myocardial infarction, may, in reality, be instances of cerebral thrombosis precipitated by fall in the blood pressure and decrease in cerebral blood flow The autopsy studies of Dozzi lend support to this view [12] If confirmed, another indication for the use of dicumarol in myocardial infarction should be recognized

These considerations suggest that, in the presence of extensive cerebral arteriosclerosis, therapeutic reduction of elevated blood pressure may not only fail to control but may actually initiate or aggravate cerebral symptoms Furthermore, since cerebral vascular disease with or without associated hypertension may produce most of the features of the syndrome generally referred to as hypertensive encephalopathy, the criteria for diagnosis of this condition should be reconsidered Hypertensive encephalopathy is generally recognized without difficulty in cases of hypertensive disease in which transient focal cerebral symptoms and other manifestations are dependent upon cerebral edema Its diagnosis then rests upon the demonstration of increased intracranial pressure as evidenced by papilledema, increased cerebrospinal fluid pressure, headache, vomiting, convulsions, and coma In many instances, however, the diagnosis must depend on the associated clinical picture Thus, transient focal symptoms occurring in a patient with previous cerebral vascular complications or in an elderly subject with evidence of generalized arteriosclerosis are probably due to cerebral arteriosclerosis, irrespective of the associated level of blood pressure On the other hand, focal cerebral symptoms in the patient with acute glomerulonephritis, eclampsia gravidarum, or hypertensive disease (associated with papilledema) are, in all probability, manifestations of hypertensive encephalopathy It is apparent that many of the cases which were in the past classified as hypertensive encephalopathy actually were instances of cerebral arteriosclerosis in which hypertension played only a secondary role There are undoubtedly instances in which both cerebral edema and cerebral arteriolar sclerosis contribute to the clinical picture In some cases, moreover, only necropsy study can clearly indicate which of these factors was responsible for the clinical symptom-complex. Fishberg concurs in this altered concept which is at variance with his original contention that the syndrome is invariably correlated with arterial

hypertension [1-13] He agrees that symptoms due to cerebral arteriosclerosis "should no longer be included in the rubric of hypertensive encephalopathy"

The medical management of vascular (hypertensive or arteriosclerotic) encephalopathy frequently presents a difficult problem in clinical medicine The authors have recently reported successful response of this syndrome to large oral doses of papaverine, having employed as high as 18 grains per day in some cases [3] Patients with cerebral vascular disease appear to show the most unequivocal response to this drug, but, even in malignant hypertension with cerebral edema, papaverine has seemed to reduce the frequency and severity of encephalopathic episodes The success of the drug undoubtedly depends on its ability, in large doses, to prevent cerebral angiospasm When extensive cerebral vascular disease exists in association with arterial hypertension, this drug, rather than measures tending to lower the blood pressure, should be relied on to control cerebral episodes

Summary and Conclusions

1 Hypertensive encephalopathy has been defined as a cerebral symptom-complex which is invariably correlated with arterial hypertension The validity of this concept is challenged by the observation that typical focal cerebral symptoms may develop with cerebral arteriosclerosis in the absence of elevated blood pressure An attempt was made, therefore, to evaluate the role played by cerebral vascular disease and arterial hypertension, respectively, in the pathogenesis of recurrent encephalopathic episodes in patients in whom both conditions coexist Four hypertensive patients with advanced cerebral arteriosclerosis who presented the characteristic clinical features of vascular encephalopathy were studied to determine the effect of reduction in blood pressure (by means of continuous caudal anesthesia) on the frequency and severity of seizures It was found that in these cases the attacks were either not improved or significantly aggravated by reduction in the arterial blood pressure It is concluded that, even in the presence of hypertensive disease, cerebral arteriosclerosis may be chiefly or solely responsible for recurrent cerebral episodes The diagnosis of hypertensive encephalopathy, therefore, must depend on the associated clinical picture and the frequent occurrence of cerebral edema

2 Inasmuch as reduction of blood pressure in the hypertensive patient is commonly associated with decrease in cerebral blood flow and persistence of a high degree of cerebral vascular tone, therapeutic or accidental restoration of normotensive levels when there is extensive cerebral vascular disease may significantly affect the blood supply to the brain. Clinical examples are cited in which such decline in the blood pressure appeared responsible for the development or aggravation of cerebral symptoms in arteriosclerotic subjects

3 Papaverine hydrochloride in large oral dosage has been found effective in controlling the symptoms of vascular (hypertensive or arteriosclerotic) encephalopathy When there is marked cerebral vascular disease associated with hypertension, this drug, rather than measures tending to lower the blood pressure, should be relied on to prevent recurrent cerebral episodes

Caudal anesthesia was administered by Dr James L. Southworth.

LICENSE REQUIREMENTS UNDER NURSE PRACTICE ACT

A recommendation has been made by the New York State Inter-Departmental Health Council to postpone the licensing requirements under the Nurse Practice Act for an additional period of one year If the present act goes into effect, hospitals will have to restrict the physical care of patients to licensed practical nurses. Since at most only a thousand are graduated from practical nursing schools each year, the supply would not be adequate for the purpose Hospital authorities fear that they would be liable for administrative negligence if they did not provide adequate nursing care as defined by the proposed statute The acute shortage of nurses has caused hospitals to employ auxiliary workers under the supervision of registered professional nurses. While there has been some improvement in the nursing situation, the number of practical and professional nurses available is still too small to dispense with the use of auxiliary workers in hospitals The law now exempts attendants in mental hospitals from licensing if adequate medical and nursing supervision is provided Similar consideration should be given to all subsidiary nursing aides in legally incorporated hospitals having adequate nursing and medical service —*Greater New York Hospital Association*

AMPUTATION IN PATIENTS WITH DIABETES MELLITUS

JAMES S WEST, M D , and E M PAPPER, M D , New York City

(From the Department of Anesthesia, New York University College of Medicine, and the Anesthesia Service, Bellevue Hospital)

ANESTHESIOLOGISTS have been conspicuously absent in discussions related to the proper management of patients with diabetes mellitus who are subjected to amputation of the lower extremity Ordinarily, anesthetic care for these patients is not deemed complicated, since the primary requirement for anesthesia is the provision of pain relief alone Although it has always been desirable to impose no further strain upon the surgical diabetic during the anesthetic period, this need has rarely seemed difficult enough of attainment to warrant extensive commentary However, since there is considerable difference of opinion among physicians interested in the surgical problems of diabetes, it seemed desirable to add the information and experience available from the viewpoint of the anesthesiologist The current lack of agreement upon the value of refrigeration, a procedure which provides surgical anesthesia, further supports the need for data collected from patients, who were serious problems, in which other forms of anesthesia were largely employed, to the almost complete exclusion of refrigeration [1–6] Furthermore, since mortality rates vary from the 4.7 per cent reported by McKittrick to figures as high as 75 per cent, the results obtained in other large clinics should help toward arriving at a satisfactory regime [1]

It was decided, therefore, to review the clinical material of Bellevue Hospital for the several reasons outlined above This institution is a large municipal hospital organized into five separate surgical services employing variations in surgical technic and utilizing different approaches to the medical management of the complicating diabetes These indigent patients were frequently unsupervised diabetics prior to entry, although not uniformly so They were undoubtedly of the "poorest risk" group The only common denominator was the anesthetic management by a single department of anesthesia which served all patients in the hospital. All cases since the establishment of the department in 1935 through 1946 are included—521 in all—with the exception of the period of July, 1942, through December, 1943 These eighteen months were arbitrarily excluded because the skeleton staffing of the anesthesia service during this part of the war years precluded the completion of adequate records It must be emphasized that the exclusion of cases in this interval extended to all surgical services and, therefore, should have no bearing on the ultimate picture The vast majority of patients were anesthetized with inhalation anesthesia, usually cyclopropane Refrigeration analgesia was rarely employed

It is not our present purpose to review in detail the medical and surgical aspects of amputations for diabetic gangrene Comment will be reserved, for the most part, to a consideration of the anesthetic regime and the presentation of clinical information obtained from reviewing the records of the patients here

The selection of anesthesia does not depend upon surgical requirements, since the operator requires pain relief only and relaxation is unnecessary Therefore, the choice of anesthesia must be governed by the presence of diabetes and the other pathologic disorders associated with this age group and partially influenced by the diabetes The most common and most important of these are the cardiovascular disorders of hypertension and arteriosclerosis

It has been pointed out that cyclopropane exerts little effect on the fasting blood sugar of diabetic patients and almost no disturbance of acid-base balance [7] Other studies from this clinic suggest that intermediary metabolism of carbohydrates is affected adversely by cyclopropane and to a lesser degree by pentothal sodium and spinal anesthesia with procaine.[8 9] The precise role these disturbances may play in the surgical diabetic has not as yet been elucidated, but, presumably, careful attention to hydration, insulin dosage, and electrolyte balance is capable of overcoming the minor defects of these agents and technics At least on the basis of clinical experience adequate medical management of the diabetic is not complicated by the administration of these agents Appropriate nerve block may be included here in the same category as low spinal anesthesia

Ether has been employed with satisfaction in many clinics as the anesthetic agent of choice in the patient with diabetes While it is realized fully that ether does serve the purpose under these circumstances, it cannot be accepted as the agent of choice in our hands except in specifically selected cases It has been conclusively demonstrated that ether elevates the blood sugar markedly and greatly facilitates the development of acidosis [10] There is ample evidence, in addition, that this agent with the single exception of the halogenated hydrocarbons interferes with

liver function to a greater degree than other general anesthetic agents These disturbances do not necessarily suggest a tragic result, but they impose considerable difficulty in metabolic control to the internist The series reported here demonstrates an undue incidence of ketosis after ether anesthesia as compared with cyclopropane In these circumstances, it seems wiser to avoid the use of ether, since other methods and agents offer a lesser degree of metabolic and acid-base disturbance Ether is chosen, if inhalation anesthesia is selected, only when there are specific contraindications to the use of the other agents The development of arrhythmia during cyclopropane anesthesia no longer necessitates abandonment of this agent in favor of ether since the demonstration of the efficacy of procaine administered intravenously in this situation [11]

Nitrous oxide has been gradually discarded since the introduction of cyclopropane because the not infrequent asphyxia exerts deleterious effects on carbohydrate metabolism which are equivalent to massive epinephrine administration Perhaps even more urgent is the need to avoid any degree of anoxia in these patients who suffer from myocardial inadequacy as well

The circulatory complications of the patient with diabetic gangrene deserve considerable stress In this connection, it is important to emphasize the prime need of avoiding anoxia This fact has been pointed out repeatedly by observers whose surgical practice includes patients with diminished cardiac reserve [12] This is, in part, a matter of judgment and, in part, a matter of technical skill in anesthesia If it is realized that all depressant drugs and anesthetic technics carry the potentiality of decreasing optimum oxygenation of the tissues, a long step in progress is achieved Inhalation agents should be administered through an unobstructed airway with adequate oxygen tension, and spinal anesthesia should be kept low enough to avoid respiratory embarrassment Regardless of the choice of anesthesia, depressant drugs for these patients are either unnecessary or may be confined to exceedingly small dosage Finally, the supine position is preferable because of the proved interference with vital capacity in other postures, a significant consideration in the diabetic patient who also has serious cardiac involvement [13]

Because of the benign influence of cyclopropane on the diabetic state, its safety and rapidity of action for patients with cardiovascular disease without alteration of cardiac rhythm, and the desirability of securing unconsciousness during amputation for psychic reasons, this agent has been the one of choice in the large majority of these surgical manipulations The last element, the emotional factor, may not loom so large in other clinics, but experience here dictates its enormous value in patients who frequently benefit by being spared the psychic trauma of witnessing or hearing events which are intimately concerned with the loss of an important body part The results obtained have justified the utilization of inhalation anesthesia with cyclopropane in admittedly bad-risk subjects

Clinical Data

Five hundred and twenty-one unselected diabetic patients observed from 1935 to 1946 who required amputation for gangrene in the lower extremities form the basis of this report

Approximately two thirds of these patients were treated prior to the large-scale availability of penicillin

In the vast majority of instances, operation was performed by a surgical resident in training, and anesthesia was administered by a member of the resident staff of the Department of Anesthesia, both under teaching supervision Forty-one of these patients died during the period of hospitalization, a total mortality of 7 8 per cent There was one death on the operating table due to asphyxia. Two hundred sixty-eight patients were subjected to amputation through the thigh with 37 deaths, a mortality rate of 13 8 per cent The remaining 253 patients had leg, foot, or toe amputations, resulting in the death of four patients or a mortality of 1 6 per cent

It is necessary to add that these mortality data refer to deaths during the period of hospitalization which was precipitated by lower-extremity gangrene No information is available to the Anesthesia Service concerning the ultimate length of survival after release from the hospital

Figure 1 summarizes some of the mortality data collected The definite difference in fatality after thigh as compared with *leg or foot* amputation is clearly indicated The influence of age upon mortality is evident from the graphic separation of the various age groups It will

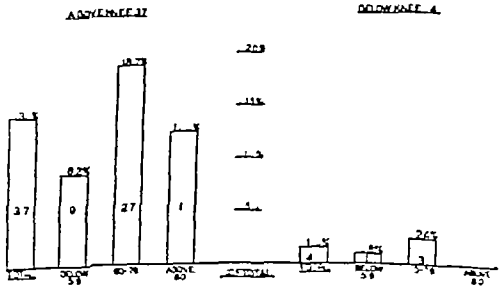

FIG 1 The mortality in the various age groups from above and below knee amputations is represented by percentage (indicated at top of each graph) and number of patients (inside graphs)

TABLE 1.—PREOPERATIVE COMPLICATIONS

	Under 59 Years		60 to 79 Years		Over 80 Years	
	Thigh	Leg and Foot	Thigh	Leg and Foot	Thigh	Leg and Foot
Arteriosclerotic cardiovascular disease	30 3% (33)	14 3% (18)	42 2% (62)	36 9% (45)	62 5% (5)	0
Hypertensive cardiovascular disease	19 2% (21)	28 5% (36)	25 2% (37)	20 3% (25)	12 5% (1)	0

be noted that more patients in the sixty to seventy-nine age group died in both major and minor types of procedures In fact, this age group accounts for approximately 75 per cent of the total mortality This is particularly significant since these patients comprise 51 per cent of the total group of 521 The separation of patients into age groups is illustrated in Figure 2

The sex distribution is not dissimilar from other series of amputations for diabetics in its preponderance of women (56 per cent)

Preoperative Complications

Cardiovascular disease due to hypertension or arteriosclerosis was an exceedingly common cause of preoperative morbidity Table 1 delineates the actual incidence of this complication. Large as the incidence was in all groups, it should be noted that the patients subjected to thigh amputation were more frequent victims of vascular disability than those whose operations were minor in character, except for the patients less than fifty-nine years of age This lone exception demonstrates a greater incidence of hypertensive disease in the minor operative series as compared with the major group This significant predisposition to circulatory crisis probably had a definite influence on the subsequent mortality Other preoperative complications were not so frequently noted and include rheumatic heart disease, pulmonary embolus, severe anemia, malignancy, acidosis, sepsis, chronic alcoholism, syphilis, psychosis, pneumonia, nephritis, and hyperthyroidism, to consider the major ones alone Although not so common, these diseases were responsible for a proportion of the deaths It is worth emphasizing the fact that 16 of the thigh cases were psychotic, a problem of enormous magnitude in management as indicated by the seven deaths which ensued

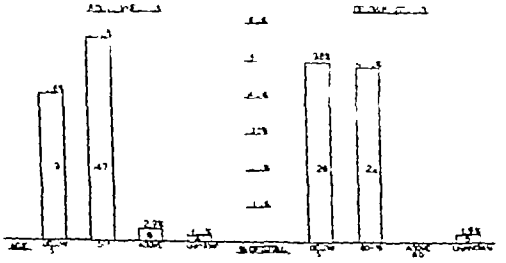

FIG 2 The age groups of patients undergoing above and below knee amputation are shown in percentage (indicated at top of each graph) and number (inside graph)

Refrigeration	5	0
Local and block	1	9
Total	268	253

* Usually cyclopropane.

Anesthesia

Table 2 summarizes the anesthetic procedures employed The large number of inhalation (usually cyclopropane) anesthesias is emphasized Premedication varied considerably throughout the period studied, but recent observations have reflected the decreasing need for depressant drugs of the opiate or barbiturate groups in elderly patients [14] At the present, premedication usually consists solely of a small dose of a belladonna drug, given for its drying effect upon tracheobronchial secretions and as prophylaxis against the reflexes initiated during operation. Most operative procedures consumed more than one hour in the thigh amputations and somewhat less in operations upon the leg or foot

Operative complications were not unusual, and shock was conspicuous by an unexpectedly low incidence (1.2 per cent)

Postoperative Complications

Major postoperative complications are summarized in Table 3 It is evident that the gross incidence of major complications is not enormous, but is extremely significant if Table 3 is compared with Table 4 Seven of the ten patients who developed atelectasis or pneumonia in the thigh group expired All 12 patients in this group who had congestive heart failure died, as did all subjects in whom systemic sepsis occurred Three of the four patients in severe ketosis did not survive, and one of the two victims of pulmonary embolization failed to recover, as did the patient with coronary thrombosis It is suggested that these complications in major surgery in the diabetic are of tremendous significance in the mortality which ensues after their occurrence.

Discussion

Although no attempt has been made to compare the various methods of anesthesia available

TABLE 3.—POSTOPERATIVE COMPLICATIONS

	Thigh	Leg and Foot	Total
Death	13 8% (37)	1 6% (4)	7 8% (41)

for amputations in the diabetic patient on the basis of experience at Bellevue Hospital, it is inevitable that such comparisons be drawn, because the clinical material is similar in risk to that described by Crossman and Allen who employ refrigeration almost exclusively, with a mortality rate of 21 per cent, in their diabetic patients.[2] The superiority of McKittrick's series is readily acknowledged and is a tribute to the coordinated efforts of all concerned in the care of diabetic patients It must also be admitted that the end results in the type of patient seen at a large charity hospital in the problem under discussion can never equal those in which patients are under constant supervision prior to admission for operation Many of our patients have had no medical care of any kind until they present themselves with gangrene

From the data presented here, the mortality in thigh amputations in diabetics of 13 8 per cent and the total mortality of all amputations in these patients of 7 8 per cent compare very favorably with those from clinics other than the New England Deaconess group and are definitely superior to the results reported for refrigeration technics in comparable patients It is suggested that, in addition to the important factors in lowering mortality presented by McKittrick, the capable management of the anesthetic period must also be included For reasons discussed, cyclopropane has been the choice in the vast majority of instances, but emphasis is directed toward the anesthetic judgment and technical skill of the trained anesthesiologist rather than toward the peculiar virtue of a single agent or technic

It is apparent that the place of refrigeration in the management of the diabetic cannot rest upon the lower mortality it affords, the protection of the patient against the effects of other anesthetic methods, or the exclusive ability to relieve pain incident to surgical manipulations with safety Its proper position in the surgical management of diabetic subjects must be evaluated in terms of purely surgical considerations, e g, the effect upon the wound itself, the influence upon the subsequent use of prostheses, etc, rather than its alleged superiority to other methods of anesthesia in assuring a successful issue That it has such value is readily apparent from the testimony of competent surgeons

Summary

1 A brief review of the anesthetic considerations in the management of diabetic patients subjected to amputation for gangrene is presented

2 Analysis of a ten-year period of experience with 521 amputations in patients with diabetes at Bellevue Hospital is offered for consideration

3 A total mortality of 7 8 per cent was observed which is divided into 13 8 per cent for patients subjected to thigh amputations as against 1 6 per cent for those whose operative procedures were in the leg or foot.

4 The influence of cardiovascular disease in the preoperative state is suggested, and other pertinent factors are considered.

5 The causes of death and postoperative morbidity are outlined

6 Commentary on the utility of cyclopropane in this series is made, together with emphasis on the favorable results as compared with the groups managed with refrigeration.

This study was completed under the direction of E. A. Rovenstine M D The authors wish to express their sincere appreciation for his valuable guidance and assistance.

ACUTE CORONARY OCCLUSION SIMULATING ACUTE ABDOMINAL DISEASE

LEONARD E FIELD, M D , LEON PORDY, M D , and ARTHUR M MASTER, M D , New York City

(From the Cardiographic Laboratory Mount Sinai Hospital)

SEVERAL patients have been encountered recently whose presenting clinical picture was presumably caused by acute intra-abdominal disease but who actually had sustained myocardial infarction due to acute coronary occlusion The association of abdominal symptoms and signs with acute coronary occlusion is well established [1] However, it is not common for the presenting symptoms to be confined entirely to the abdomen and, therefore, to simulate an acute intra-abdominal condition. Accordingly, four cases are described to re-emphasize the necessity for taking routine electrocardiograms early in all patients with acute upper abdominal findings, despite the absence of chest symptoms

Case Reports

Case 1 —S W , a thirty-seven-year-old man, had suffered episodes of mild "indigestion" and fainting spells for years On January 19, 1946, he developed a feeling of nausea which lasted an hour and a half and which came on after drinking cold milk. Five days later, on January 24, the patient again became nauseated and approximately an hour later experienced severe epigastric and periumbilical pain, which subsequently became diffuse throughout the abdomen He was hospitalized the same day

Upon admission, January 24, 1946, the patient appeared acutely ill His temperature was 98 6 F , pulse 72, blood pressure 110/70 mm. Hg The heart was not enlarged, the sounds were of good quality, and there were no murmurs. Epigastric tenderness and spasm of the upper rectus muscle were present, the lower abdomen was soft and not tender There was no rebound tenderness The blood hemoglobin level and red cell count were normal. However, there was a leukocytosis of 22,300 cells per cu mm., of which 86 per cent were neutrophils including 16 per cent nonsegmented forms The clinical impression was a penetrating peptic ulcer No air was demonstrable beneath the diaphragm by roentgenogram. On the following day the temperature was still low, but the white blood count had risen to 25,100 cells per cu. mm. with 83 per cent neutrophils, of which 24 per cent were nonsegmented and 2 per cent juvenile forms The blood pressure was 125/75 Additional x-ray examination of the chest and abdomen were still normal, but examination by one of the attending surgeons now disclosed a pleuropericardial friction rub near the apex.

Because of the friction rub, on January 26, thirty-six hours after admission, an electrocardiogram was made which pathognomonically revealed recent myocardial infarction due to acute coronary occlusion together with acute pericarditis. These changes consisted of a deep Q wave in lead 1, a smaller Q wave in lead 2, a very small R wave with a deep S wave (a Q equivalent) in lead 4, striking elevation of the RS-T segment in leads 1, 2, and 4, and slight elevation of the RS-T segment in lead 3 with diphasic T waves in leads 1 and 4 (FIG. 1)

The patient's course was uneventful. The friction rub disappeared on the seventh day of illness, only slight fever developed, moderate tenderness was present in the right upper quadrant, the sedimentation rate was rapid. Progressive characteristic changes occurred in repeated electrocardiograms A tracing taken on February 28 with multiple chest leads showed the very small R wave and deep S wave in leads CF 1 to 5 and a deep QS in CF 6, the T wave was inverted in CF 4 to 6 By July 1, T_1 was less deeply inverted, and T_2 and T_4 had become upright

Follow-up examination disclosed no cardiac enlargement, slight tenderness in the right upper quadrant of the abdomen, reversal of pulsation of the lower third of the left ventricle, characteristic of a large infarct on fluoroscopy, and a normally functioning gallbladder on x-ray Occasional epigastric pain recurred, and about four months after his acute attack the patient became aware of occasional pressure in the chest The patient was hyposensitive to the Libman pain test

Case 2 —J K., a fifty-six-year-old physician, had a history of a twelve-year period of intolerance to fatty food, belching, abdominal distention, and oc-

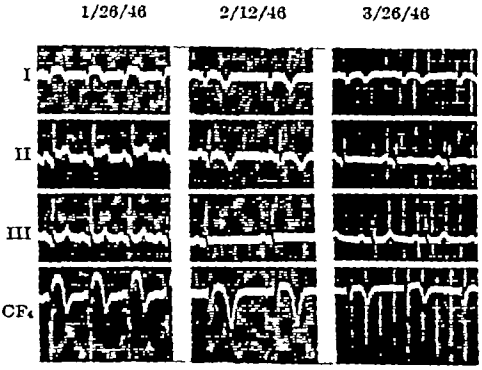

FIG 1 1/26/46 Pathognomonic electrocardiographic pattern of acute anterior wall infarction with pericarditis Deep Q in leads 1 and 4, with RS-T distinctly elevated in leads 1, 2, and 4. RS-T_3 slightly elevated. $T_{1,4}$ terminally inverted.
2/12/46 RS-T segments less elevated. $T_{1,2,4}$ deeply inverted
3/26/46 RS-T segments isoelectric. $T_{1,4}$ less inverted. T_2 upright.

casional mild epigastric and right upper quadrant pain The pains had increased in frequency during the six months prior to admission. Prompt relief was usually obtained with milk or water Roentgenograms of the gallbladder and gastrointestinal tract in October, 1947, disclosed only slow emptying of the gallbladder On December 25, 1947, the patient experienced a particularly severe attack of squeezing epigastric pain that required morphine and atropine for relief *Similar episodes recurred on* the following two days, and, since the pain persisted, the patient was hospitalized on the fourth day The clinical impression at that time was acute disease of the gallbladder or pancreas

Upon admission to the hospital on December 28, 1947, the patient's temperature was 100 F, pulse 106, and blood pressure 170/110 The heart was not enlarged and seemed normal. There was tenderness in the epigastrium and right upper quadrant, the lower margin of the liver was palpable 2 cm. below the costal margin, a finding which had long been known The white blood cell count was 9,450 per cu. mm. The sedimentation rate was 14 mm. in one hour, this subsequently rose to 40 mm. in one hour Blood and duodenal amylase, icterus index, alkaline phosphatase, and cephalin flocculation tests were normal, indicating normal function of the pancreas gallbladder, and liver

On December 29, 1947, an electrocardiogram showed abnormalities indicating myocardial infarction of the anterior wall due to acute coronary occlusion (Fig 2) These consisted of deep Q waves in leads 1 and 4 and elevation of the RS-T segment in lead 1, with corresponding depressions in leads 2 and 3 The T waves were inverted in leads 1 and 4 Progressive changes occurred in subsequent tracings

The patient's course was uneventful. He experienced no further pain, and his blood pressure fell to 130/80 which the patient stated was his normal level He was hyposensitive to the Libman pain test.

Case 3.—G B, a man of fifty, had been subject to attacks of indigestion for about two years These consisted of pyrosis, belching, and dull epigastric pain not related to meals He frequently noted a feeling of fullness in the epigastrium and occasionally experienced some shortness of breath on walking which was associated with the appearance of a prominent bulge in the midepigastric wall Roentgenographic examination of the gastrointestinal tract one year ago was said to have been normal The patient was advised to have a ventral hernia repaired On January 10, 1948, a few days before this was to have been performed, the patient was suddenly seized with a severe attack of nonradiating epigastric pain This developed shortly after a meal of crackers, thick cream, and eggs

The following day, January 11, the patient was admitted, ambulatory, to the hospital. He now complained only of a persistent dull ache in the epigastrium. The clinical impression was that of penetrating peptic ulcer Examination disclosed diastasis of the rectus muscle in the epigastrium which admitted three fingertips, tenderness over this region, and a marked bulge on straining The blood pressure was 115/80, six months previously the systolic pressure was known to have been 154. The following day the temperature rose to 102.6 F and the pulse 100 Gastrointestinal x-ray examination on this date revealed a tiny hiatus hernia and a constant deformity of the duodenal bulb The urine was concentrated to a specific gravity of 1.037 and contained one plus albumin and occasional red and white cells A leukocytosis of 20,000 cells per cu mm. with 81 per cent neutrophils was found on January 13 On January 14, an electrocardiogram showed the typical pattern of myocardial infarction of the posterior wall due to acute coronary occlusion (Fig 3) This consisted of a small Q in lead 2 and a deep Q in lead 3, elevated RS-T segments in leads 2 and 3 with a depression in leads 1 and 4. The T wave was inverted in leads 2 and 3 In addition, auriculoventricular dissociation was present

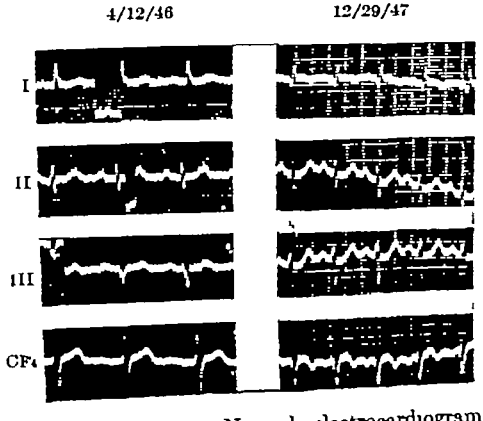

FIG 2 4/12/46 Normal electrocardiogram. 12/29/47 Classical pattern of acute coronary occlusion with *anterior* wall infarction. Q waves present in leads 1 and 4 with corresponding RS-T elevations in these leads. $T_{1,4}$ inverted.

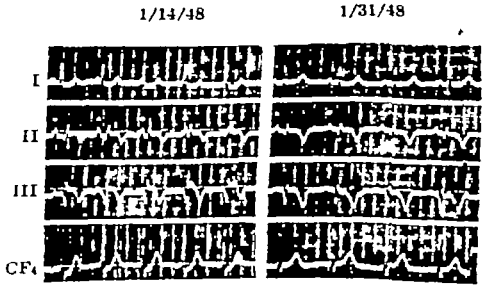

FIG 3 1/14/48 Typical pattern of myocardial infarction of the posterior wall due to acute coronary occlusion Small Q_2 and deep Q_3 present RS-$T_{2,3}$ elevated, RS-$T_{1,4}$ depressed. $T_{2,3}$ inverted In addition there is an auriculoventricular dissociation (P waves indicated by white dots)

1/31/48 RS-T segments isoelectric $T_{2,3}$ more deeply inverted.

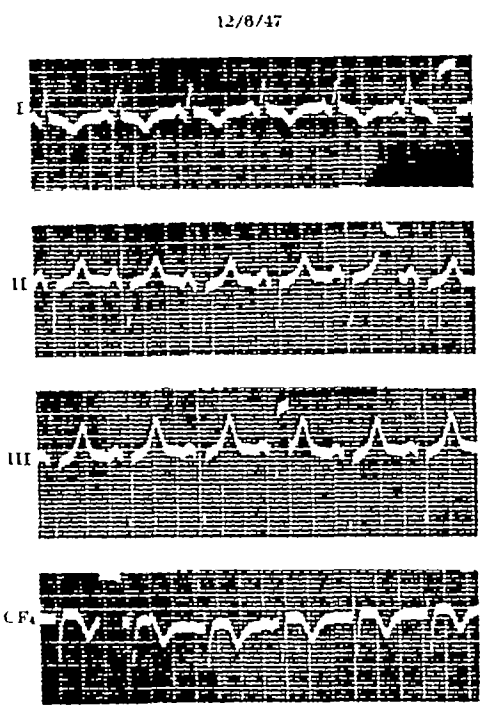

FIG 4. 12/6/47 Electrocardiogram suggests infarction of the anterior wall due to acute coronary occlusion Small Q present in lead 1 RS-$T_{1,4}$ slightly elevated RS-T_3 slightly depressed $T_{1,4}$ inverted

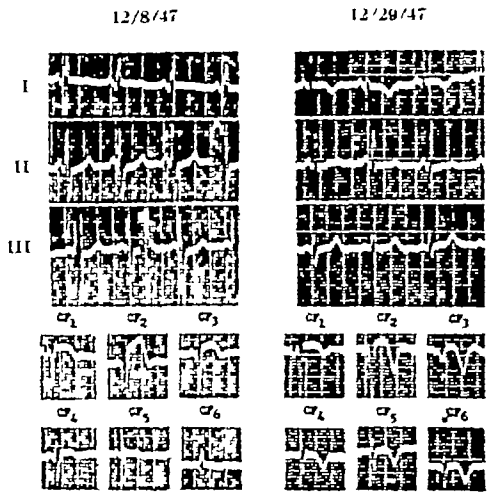

FIG 5 12/8/47 Deep Q present in $CF_{1,-,5}$ RS-T_2 slightly depressed RS-T_3 more depressed RS-T elevated in $CF_{1,2,3,4}$ T_1 no longer inverted T wave in chest leads diphasic or slightly inverted 12/29/47 $S_{2,3}$ now small. RS-$T_{1\ 2,3}$ isoelectric RS-T segment in $CF_{1,-,3}$ only slightly elevated T wave now deeply inverted in leads 1, CF_{1-4}

The patient's course was uneventful, after subsidence of the abdominal pain, he remained asymptomatic Low-grade fever was present for a week His blood pressure dropped to 100/70, and the heart sounds were noted to be faint The usual progressive changes developed in his electrocardiogram the RS-T segments became isoelectric, and the T wave in leads 2 and 3 more deeply inverted, the auriculoventricular dissociation disappeared Roentgen examination of the gallbladder on two occasions was normal, and a repeat gastrointestinal x-ray series subsequently did not definitely establish the diagnosis of duodenal ulcer This patient was a hyposensitive individual according to the Libman test and at no time experienced supradiaphragmatic pain

The patient was observed after discharge from the hospital. On March 15 he first began to complain of precordial heaviness on walking On April 25 he died suddenly

Case 4.—T B, a woman of sixty-four, had experienced two episodes of right upper quadrant, cramplike pain a few years ago For a week prior to hospitalization she complained of anorexia and of a loss of her sense of well-being On December 4, 1947, she developed intermittent cramps in the right upper quadrant of the abdomen radiating to the epigastrium, a sense of epigastric pressure, repeated vomiting of clear fluid and fever of 103 F The family thought that the patient appeared jaundiced and that her urine was dark On the following day the right upper quadrant pains became more severe, the epigastric pressure seemed to radiate substernally for about an hour, and the temperature rose to 104 F The attending physician made a diagnosis of acute cholecystitis and recommended hospitalization, which was accomplished the same day

Upon admission, December 5, the patient's temperature was 101 6 F, pulse 120, respirations 24 and blood pressure 110/74 The heart sounds were good, the rhythm was regular The abdomen was soft but diffusely tender The urine contained no bile The leukocyte count was 15,000 cells per cu mm with 84 per cent neutrophils, the sedimentation rate was 53 mm. in one hour

On December 6 fluoroscopy and roentgenogram of the chest were not abnormal. An electrocardiogram on this date showed a small Q in lead 1, slightly elevated RS-T segments in leads 1 and 4 with slight depression in lead 3 (Fig 4) The T wave was inverted in leads 1 and 4 These changes suggested anterior wall infarction due to acute coronary occlusion. This was confirmed two days later, December 8, when multiple chest leads disclosed a deep Q wave in leads CF 1, 2, 3, elevation of RS-T in CF 1, 2 3, 4, a greater depression of RS-T_3, T_1 was no longer inverted, and the T waves in the chest positions were only slightly inverted

On December 15 the T waves became inverted once again in leads 1 and CF 1-6, T_2 was diphasic The temporary reversion of the T waves toward normal seen in the tracing taken December 8 is not uncommon (Fig 5) Jaffe, Master and Kalter have noted partial or complete return of the electrocardiogram to normal within a few days after the onset of

acute coronary occlusion.[3] This patient subsequently showed the usual progressive changes in the electrocardiogram.

The patient's course was not remarkable except for a period of somnolence, all pain disappeared on the second day A gallbladder examination prior to admission had shown nonvisualization of the gallbladder She was normosensitive to the Libman pain test

Discussion

As we have stated, the purpose of this report is to demonstrate that in actual acute coronary occlusion the pain and symptoms may be entirely or practically altogether below the diaphragm, not in the chest The knowledge that the clinical picture of acute coronary occlusion may present abdominal findings, in addition to thoracic signs, is not new Herrick mentioned this in his original article published in 1912 and referred to earlier papers of Obrastzow and Straschesko and of Engelhardt [1] In 1918, Levine and Tranter described two cases that closely resembled an acute intra-abdominal disease because of the absence of supradiaphragmatic signs and symptoms [3] Their first patient died during induction of ether anesthesia. In their second case laparotomy was deferred because of glycosuria and ketosis, but the patient died the next day after developing heart block. Subsequently, many authors emphasized the point that pain in coronary disease may be referred to the abdomen at least during the early hours [4–11] Libman in particular stressed the fact that atypical clinical pictures in acute coronary occlusion are prone to occur in hyposensitive individuals [12] It may be noted that three of our cases were hyposensitive to the Libman pain test, Case 4 was normosensitive

While epigastric localization of pain is not uncommon as the original site of pain in myocardial infarction, Bean having noted such in 29 instances of 144 cases, the pain almost always radiates substernally or to the precordium and subsequently remains there [13] Levine and Brown, however, stated that occasionally the pain may be entirely confined to the abdomen.[7] This was true in three of our four cases In Case 4, epigastric pressure sensation radiated substernally for about an hour on the second day The pain may be diffuse or even present in the lower abdomen.[14]

Larkin recently reported that some abdominal symptoms—nausea, vomiting or pain—occurred in 20 out of 92 patients, 91 of whom had acute coronary occlusion and one a ruptured aortic aneurysm.[11] Furthermore, the mortality rate in this group was higher than in cases without abdominal symptoms Eleven of his cases had only abdominal symptoms

It may be mentioned here that in our patients occurrence of abdominal pain bore no relation to the site of the myocardial infarct In three cases it was anterior and in the other case posterior

"Abdominal angina" is a term occasionally encountered in medical literature This syndrome is undoubtedly due to pain referred from the heart either in true coronary occlusion or in simple angina pectoris rather than to arteriosclerosis of the abdominal vessels [6,8 15]

Among the diseases that may be simulated by acute coronary occlusion are acute cholecystitis, acute pancreatitis, perforating peptic ulcer, splenic infarction, renal colic, tabetic crisis, acute intestinal obstruction, and adrenal hemorrhage Nausea, vomiting, upper abdominal tenderness, spasm, and even rigidity are common to all Generally, however, in myocardial infarction dyspnea is more apt to be present, likewise, after the onset, some chest symptoms, as substernal tightening, almost always occur Nevertheless, despite the clinical acumen of the attending physician, actually the indispensable diagnostic procedure in the presence of this mimicry of symptoms and signs is the electrocardiographic pattern.

It need hardly be mentioned that acute coronary occlusion can coexist with an acute abdominal episode We have observed a man of seventy-four who developed acute cholecystitis eight days after the onset of a posterior wall infarction due to acute coronary occlusion. The time relationship, indeed, may be exceedingly close, as in the autopsied case reported by Branwood of an acute coronary occlusion which seemed to follow within an hour of a perforated duodenal ulcer [16]

An additional perplexing situation is to be noted Acute abdominal disease may secondarily affect the heart, inducing acute coronary insufficiency This must not be confused with the main subject of this report, which is the converse—namely, acute coronary occlusion in which the complaints are in the abdomen altogether or chiefly However, it is important to realize the magnitude and the principles underlying acute coronary insufficiency so that a clear distinction will be maintained between it and coronary occlusion Acute intra-abdominal disease may act as a precipitating factor in producing coronary insufficiency The usual mechanism in such an instance is a diminution of coronary blood flow resulting from lowered blood pressure and diminished cardiac output incident to shock, peripheral collapse, or hemorrhage The electrocardiographic changes that occur in such conditions must be differentiated from those due to primary cardiac disease, that is, myocardial infarction due to coronary

occlusion This is particularly important since acute intra-abdominal disease may, in addition to the electrocardiographic changes, produce chest pain, shock, tachycardia, and fall in blood pressure These features have been observed in the presence of acute pancreatitis, acute cholecystitis, renal and biliary colic, perforating and penetrating peptic ulcer, gastrointestinal hemorrhage, splenic infarction, acute intestinal obstruction, hiatus hernia, acute peritonitis, etc [14,15,17–21]

Proper evaluation of the electrocardiogram in acute coronary occlusion and in acute coronary insufficiency depends in great measure upon the presence or absence of Q waves and RS-T segment deviations In acute coronary insufficiency there are found, characteristically, RS-T segment depressions and T wave changes in one or more leads, not associated with abnormal Q waves and RS-T segment elevations Such alterations are generally transitory In acute coronary occlusion, on the other hand, the criteria are abnormal Q waves, RS-T segment elevations, and abnormal T waves

Painful stimuli arising from an area of ischemia in the heart muscle travel in the visceral afferent cardiac nerves to the cardiac plexuses and thence to the upper four or five sympathetic ganglia Thereafter they enter the spinal cord usually in the first to fourth thoracic segments, and subsequently pain is referred back to the corresponding dermatomes (precordial, substernal, and left arm areas) However, sensory impulses from the heart may reach different levels of the cord, anywhere from the third cervical to the tenth thoracic vertebrae [22,23] It has been suggested that this may be due to the presence of accessory visceral fibers from the heart Accordingly, pain may be referred to these other corresponding dermatomes and hence be confused with diseases of viscera which normally transmit pain impulses to these levels It is likely that previous disease of such viscera predisposes to increased sensitivity, and the cardiac ischemia reaction serves as a trigger mechanism It has been pointed out that the pain of coronary disease occurring in a patient with previous peptic ulcer, for example, may radiate to or originate in the upper abdomen.[24]

In view of the diagnostic problems encountered it is evident that an electrocardiogram should be taken early in all instances of acute upper abdominal signs and symptoms whether or not chest findings are present More important, procedures such as roentgenograms of the gallbladder and gastrointestinal tract should be deferred until electrocardiographic analysis has been completed

Summary and Conclusions

1 Four cases of acute coronary occlusion with the clinical picture of acute intra-abdominal disease are reported In three of the patients the pain remained entirely confined to the abdomen In each instance the diagnosis was made by the electrocardiogram

2 Such atypical clinical patterns are prone to develop in hyposensitive individuals

3 The site of the myocardial infarct, anterior or posterior, has no bearing on abdominal reference

4 Not only may acute coronary occlusion simulate abdominal disease, but the converse occurs—abdominal disease may clinically resemble acute coronary occlusion and produce electrocardiographic changes characteristic of acute coronary insufficiency

5 The electrocardiogram is the principal diagnostic procedure It should be taken early in every instance of upper abdominal symptoms before subjecting patients to gastrointestinal or gallbladder roentgenograms and similar procedures, and, of course, to operation

CEREBRAL COMPLICATIONS RESULTING FROM HYPERTENSION CAUSED BY VASOPRESSOR DRUGS IN OBSTETRICS

BARNETT A GREENE, M D , and JULIUS BARCHAM, M D , Brooklyn, New York

(From the Departments of Anesthesiology, Brooklyn Women's, Adelphi, and Unity Hospitals)

THIS report is intended as a caution against the inadvertent combination of vasopressor drugs in obstetrics By producing an acute hypertension, these have caused convulsion, hemiplegia, or severe persistent headache

Posterior pituitary extract and ergonovine are used in obstetrics without fear of a pressor effect which is uncertain and mild Indeed, the opposite action, the production of a shocklike condition by posterior pituitary extract, has been reported frequently The pressor action of posterior pituitary extract and ergonovine deserves special consideration, however, whenever ephedrine sulfate, neosynephrin hydrochloride, or any vasoconstrictor has been or is likely to be used in an obstetric patient The potency of the combination of vasoconstrictor drugs, with posterior pituitary extract especially, is too little appreciated Beck and Ball encountered an instance of convulsion, severe headache, and acute hypertension during spinal anesthesia for cesarean section and three cases of severe headache and hypertension during spinal anesthesia for vaginal delivery [1] These episodes were attributed to sensitivity to ephedrine and epinephrine

No consideration was given to the probable influence of the oxytocic drugs undoubtedly used at some time during the delivery Torrie, reporting a series of cesarean sections under spinal anesthesia, simply mentions the "blood pressure which in some cases reached 180 or 200 mm systolic" [2]

The use of ephedrine or neosynephrin is becoming more common in obstetric patients because of the greater application of caudal and spinal analgesia to vaginal and abdominal delivery Ephedrine or neosynephrin is injected before or during spinal or caudal analgesia to prevent or correct the hypotension frequently caused by the extensive sympathetic block. When these drugs are preceded or followed within a half hour by posterior pituitary extract and/or ergonovine the elevation of blood pressure may be marked and abrupt We observed a significant rise in six cesarean sections and eight vaginal deliveries The rise in these cases ranged between 50 to 100 mm. Hg systolic pressure The result has always been a severe headache One patient developed a hemiplegia as described in the following case report

Case Report

A thirty-seven-year-old Negro primipara was subjected to an extraperitoneal cesarean section because of cephalopelvic disproportion after a twenty hour test of labor She was tall, muscular, weighed 192 pounds, and was in good condition The blood serologic test was negative, antiluetic therapy had been received in 1940 Her blood pressure had been normal throughout pregnancy and was 120/80 mm Hg just before anesthesia.

The anesthesia was a fractional spinal with 90 mg procaine hydrochloride in 45 mg per cc concentration Ephedrine sulfate, 50 mg , was injected subcutaneously ten minutes before the anesthesia The blood pressure fell to 90 mm Hg systolic, and the pulse rose from 100 to 120 when the fetus was delivered, which was thirty minutes after the preoperative ephedrine. Neosynephrin hydrochloride 0 5 cc , was administered subcutaneously to secure a gradual, sustained return of blood pressure to normal with a decrease of the tachycardia. The delivery of the baby was followed by a moderate loss of blood At the request of the surgeon 0 5 cc of Infundin (5 units posterior pituitary extract) by the subcutaneous route and 1 cc of Ergotrate by vein were injected. Unknown to the anesthetist, the surgeon had injected 1 cc of Infundin (10 oxytocic units) into the uterine wall just before incising it. Ten minutes after the birth of the child and five minutes after the anesthetist's injections, the blood pressure rose to 220 mm. Hg systolic. The hitherto quiet patient complained bitterly of headache while her systolic blood pressure ranged between 180 and 220 during the following thirty minutes in spite of an addition of intraspinal procaine, 45 mg , and elevation of the head of the table to lower the blood pressure. The systolic tension then dropped to 100 mm. Hg aided by the moderately excessive blood loss. The patient became comatose about one-half hour after the birth of the baby at the peak of the acute hypertensive episode. The coma was attributed at the time to the morphine sulfate $^1/_8$ grain (7 5 mg) and scopolamine $^1/_{100}$ grain (0 2 mg.) administered immediately after the evacuation of the uterus The mother was returned to bed still in coma. On the next day the patient showed a right hemiplegia, right facial palsy of central origin, confusion, asphasia and fecal and urinary incontinence She improved, but was discharged still showing the hemiplegia and asphasia. These have persisted

Discussion

The anesthetist was unaware of the custom of this surgeon to inject posterior pituitary extract into the uterus We have long considered this route as potentially dangerous because it easily

allows the injection to be intravenous or to act very much like one [2] In fact only rarely have we seen an obstetrician test the intrauterine injection against possible intravenous location Furthermore, this route is illogical in view of the fact that contraction of the whole uterus depends on circulatory distribution of the drug to the entire organ and not on local diffusion Failing to prevent the intrauterine injection but aware of it, the anesthetist would have omitted any preparation of whole posterior pituitary extract in complying with the surgeon's request to inject an oxytocic drug He would have substituted Pitocin which does not contain a significant quantity of the vasopressor factor

Melville proved the synergism of posterior pituitary extract and ephedrine in elevating the arterial blood pressure [4] The vasoconstrictor power of posterior pituitary extract on capillaries and arterioles, especially the former, is normally compensated by a decrease in heart rate and cardiac output as demonstrated by Grollman and Geiling [5] Ephedrine prevents the heart from mitigating the peripheral vasoconstrictor action of whole posterior pituitary extract Furthermore, ephedrine adds its own effect by a marked increase of cardiac output and by arteriolar and venous constriction. The resultant rise in blood pressure is consistently greater than that produced by either drug alone Dripps and Deming have demonstrated systolic blood pressure levels well over 200 mm Hg , lasting several hours and accompanied by severe headache, following the combined use of 10 units of pitressin and 50 mg of ephedrine before spinal anesthesia [6] This potent pressor combination, in smaller doses than that injected in this case, has been employed by one of us in special cases of spinal anesthesia since 1940 with good results and no complication.[3]

Another factor which tends to augment the rise of blood pressure is the "autotransfusion" effect of the gravid uterus when the fetus and placenta are delivered and oxytocics are injected The squeezing out of a significant quantity of blood into the general circulation and the decrease in the size of the uterine vascular bed tend to cause an elevation of blood pressure, especially if it is low at the time of delivery This observation also has been noted by others [7]

Parenthetically, it may be added that this case provides another reason for the delegation of all drug management in the operating or delivery room to the anesthetist At least, he should be deliberately informed of the surgeon's intention to use any potent pharmacologic agent Only in this way can we avoid the harmful pharmacologic combinations familiar to the anesthesiologist Other similar combinations, now well known, have occurred in the practice of gynecology and obstetrics with fatal results, e g , posterior pituitary extract during cyclopropane anesthesia and epinephrine during chloroform or cyclopropane anesthesia [8–10]

A drug-induced acute hypertension may be seen during vaginal delivery or uterine dilatation and curettage for incomplete abortion under caudal or spinal analgesia, for here too ephedrine or neosynephrin is sometimes required to prevent or treat hypotension. When whole posterior pituitary extract and/or ergonovine is injected, the effect on blood pressure may be quite marked if ephedrine or neosynephrin has been injected within the preceding thirty minutes We observed eight such incidents until we used Pitocin instead of whole posterior pituitary extract and injected ergonovine intramuscularly instead of intravenously Fortunately, these episodes of acute hypertension during vaginal delivery have caused only severe headache The headache is quite disturbing, nevertheless, inasmuch as it is very painful and may remain six hours or more, and occasionally for days The headache depends more on the rapidity of the rise than on the maximum height of the systolic blood pressure Patients have cried out with pain when the systolic blood pressure rose abruptly to 160 mm Hg

The persistence of the headache for hours or days after the blood pressure has returned to normal indicates that the trauma produced by the acute stretching of the cranial arterial walls continues after the recession of the hypertension

Ergonovine malate (Ergotrate) in itself causes little or no rise in blood pressure when injected intravenously in man, despite its ability to cause vasoconstriction [11] The presence of ephedrine, however, permits intravenous Ergotrate to cause a 60 mm. Hg rise in systolic blood pressure We have observed this repeatedly Because of the demonstrated greater effect of ephedrine with posterior pituitary extract, we are inclined to be more cautious with this combination than with ergonovine-ephedrine

Treatment of the acute hypertension should be immediate. Beck and Ball have used amyl nitrite inhalation [1] We have tilted the table from the usual Trendelenburg or horizontal position desired by the operator to a slight Fowler's position. If the patient was under fractional spinal anesthesia, another dose of procaine was injected into the spinal canal Intravenous pentothal sleep was produced in three instances to obtain the mild antagonistic effect of a barbiturate against excessive peripheral vasoconstriction and to sedate the patient in distress This last measure has always been successful in moderating the hypertension It

was not applied in the case which developed hemiplegia

Summary and Conclusions

1 Hemiplegia, convulsion, and severe headache have been observed as results of the acute hypertension induced by synergistic pressor action of posterior pituitary extract and ergonovine with ephedrine or neosynephrin during spinal and caudal analgesia in obstetrics A case of hemiplegia due to drug-induced hypertension during cesarean section is reported

2 Ergonovine shows a regular but mild pressor effect after intravenous injection in an ephedrinized patient Its synergistic action should be regarded as possibly dangerous when used simultaneously with posterior pituitary extract in a patient under the influence of ephedrine or neosynephrin

3 Whole posterior pituitary extract should be used cautiously in the presence of ephedrine or neosynephrin and vice versa Pitocin is the preferred oxytocic if a pituitary preparation is desired

4 The intrauterine injection of posterior pituitary extract is dangerous and unnecessary

MEDICAL SOCIETY OF THE COUNTY OF MONROE

The following "plan" is officially sponsored by the Monroe County Society Compulsory health insurance is a major issue of the 81st Congress The *medical profession of Monroe County is unalterably* opposed to government control of medicine.

We oppose the proposed governmental health insurance plans principally because of (1) greater expense, (2) less efficiency, and (3) inability to meet local needs It will protect only the employed and not the indigent for whom it is intended

We propose an extension of Genesee Valley Medical Care as rapidly as our actuarial experience justifies This is the voluntary insurance plan, *initiated* by the Monroe County Medical Society in 1945, for surgical and obstetrical care We have already proposed to them a revision which calls for a service plan, with an income ceiling, to include surgical, obstetrical, and in-hospital medical care It anticipates G V M C as a member of the newly formed national enrollment agency which will provide national coverage for those firms and unions desiring it Plans for these improvements are going forward as rapidly as possible.

We propose that the indigent be taken care of by plans administered locally and financed locally, wherever possible

We propose whatever extension of hospital insurance seems indicated by local needs. We propose complete community support in the current hospital drive which will give the area 359 additional beds and extra clinic facilities

We propose continued growth of our Medical Service Bureau, which secures prompt medical care twenty-four hours a day for patients not able to reach their own doctor, or who have no physician of their own This service covers Monroe County

We admit that as in any plan involving the human element, there are a few weaknesses, and it is our purpose to remedy such deficiencies, as far as possible believing that these can best be adjusted on the local level to meet local situations

We should like to remind you that there is confusion in regard to the cost of hospital care and medical care, and to make it clear that the doctors have no control over hospital costs and are as concerned as the patient over the increase necessary in hospital costs. This increase is obviously due to the general increase in cost of food, help, and maintenance. If the present inflationary schedules continue, temporary government subsidies to hospitals may be indicated

We would favor legislation, State, if possible, for the care of chronically disabling diseases which cause an intolerable burden on the sufferers and their families, and the extension of grants-in-aid for the building of hospitals in communities not able to provide adequate hospital facilities, as are presently being provided in the Hill-Burton Bill

We believe that the rapid growth of voluntary insurance plans in the last three years is conclusive evidence that private enterprise in this field is successful.

We further believe that the extension of these plans in areas lacking adequate medical care facilities, together with new hospitals, will draw physicians to these areas —*January 27, 1949*

CTICAL ASPECTS OF CONTROL OF DICUMAROL THERAPY

ARD E BLUMENTHAL, M D , Hempstead, New York

E value of the anticoagulant drug dicumarol ,3′-methylene-bis (4-hydroxycoumarin)] in reatment of thromboembolic disease has clearly demonstrated in recent years The se of this paper is to emphasize some practi- pects of the control of dicumarol therapy are of particular interest to the clinician ises the smaller hospitals

orts from the Mayo Clinic within re- years have revealed that in cases of non- pulmonary embolism or infarction the nce of subsequent phlebothrombosis, bophlebitis, and pulmonary embolism or tion could be reduced from 43 8 per cent to cent by dicumarol therapy, moreover, the nce of subsequent fatal pulmonary embol- as reduced from 18 3 per cent to 0 3 per cent ises of postoperative thrombophlebitis and othrombosis the incidence of fatal pul- ry embolism was decreased from 5 7 per to 0 by dicumarol therapy [1] During the two years a controlled study on the effective- of dicumarol in acute myocardial infarction een carried out at 16 large hospitals through- he country under the auspices of the Ameri- Heart Association and the U S Public th Service Dr Irving S Wright, chair- of this cooperative study, recently revealed statistical analysis of the first 800 cases gave ollowing approximate gross results

eath in the control series	24%
eath in the dicumarol-treated series	14 9%
romboembolic complications per 100 cases	
In the control series	36 per 100
In the dicumarol-treated series	14 per 100

Of these 14, seven were while the patients were not under effective levels of treatment, either because they had not yet received any anticoagulant or because the complication came on before sufficient time had passed for the anticoagulant to be effective [2]

arious criteria for calculating the dose of marol have been described in the literature not generally appreciated, however, that in rast to a drug such as insulin, which is pre- ed daily on the basis of blood and/or urinary ose determinations, quantitative chemical s, dicumarol is prescribed daily on the basis biologic assay, the prothrombin determina-

A blood glucose report of 100 mg per cent 50 mg per cent from a number of laboratories a relatively constant significance, the dose of lin would be essentially the same regardless he laboratory in which the glucose determination was made A prothrombin time report of thirty or forty seconds from several laboratories may indicate widely varying prothrombin concentrations Therefore, the dose of dicumarol might have to vary considerably, depending on the laboratory which performed the test It is not correct or safe, therefore, for a clinician to base the dosage of dicumarol on one or another of the many prothrombin time schedules described in the literature

Dicumarol is administered in single daily doses on the basis of the prothrombin concentration of the plasma previously determined on the same day The only test of prothrombin concentration available for routine clinical use is the one-stage Quick procedure or one of its modifications Prothrombin concentration is estimated by the rate at which oxalated plasma clots when thromboplastin and ionized calcium are added to it The relationship between prothrombin concentration and the clotting time or "prothrombin time" is hyperbolic, but the exact shape of the hyperbola varies considerably with the nature of the thromboplastin used, the calcium concentration, and the diluent in which the prothrombin is dissolved

The calcium concentration and the diluent can be relatively easily standardized, but unfortunately there is not available a universally standard thromboplastin There are several reasons for this First, thromboplastin is a dried extract derived from various tissues of the body, particularly the brain or lung Most workers use either rabbit-brain or rabbit-lung thromboplastin, others have used human brain, horse brain, and even the venom of the Russell viper Each type of thromboplastin has its own clotting characteristics Second, there are differences in the methods of extraction. Some workers extract the original tissue with acetone, some do not, some workers pulverize the dried extract, others do not Extraction with acetone produces a more potent thromboplastin, pulverizing the extract produces a less potent thromboplastin The final step in extracting the thromboplastin is to suspend it in saline, and heat the suspension over a constant temperature water bath for a fixed period of time, during which time the suspension is stirred Various workers use temperatures ranging between 37 and 56 C , the time of heating generally ranges between ten and fifteen minutes, the amount of stirring varies in the different technics Generally speaking, with a higher temperature, longer heating, and more vigorous stirring, the resultant thromboplastin

was not applied in the case which developed hemiplegia.

Summary and Conclusions

1. Hemiplegia, convulsion, and severe headache have been observed as results of the acute hypertension induced by synergistic pressor action of posterior pituitary extract and ergonovine with ephedrine or neosynephrin during spinal and caudal analgesia in obstetrics. A case of hemiplegia due to drug-induced hypertension during cesarean section is reported.

2. Ergonovine shows a regular but mild pressor effect after intravenous injection in an ephedrinized patient. Its synergistic action should be regarded as possibly dangerous when used simultaneously with posterior pituitary extract in a patient under the influence of ephedrine or neosynephrin.

3. Whole posterior pituitary extract should be used cautiously in the presence of ephedrine or neosynephrin and vice versa. Pitocin is the preferred oxytocic if a pituitary preparation is desired.

4. The intrauterine injection of posterior pituitary extract is dangerous and unnecessary.

MEDICAL SOCIETY OF THE COUNTY OF MONROE

The following "plan" is officially sponsored by the Monroe County Society. Compulsory health insurance is a major issue of the 81st Congress. The medical profession of Monroe County is unalterably opposed to *government control of medicine.*

We oppose the proposed governmental health insurance plans principally because of (1) greater expense; (2) less efficiency; and (3) inability to meet local needs. It will protect only the employed and not the indigent for whom it is intended.

We propose an extension of Genesee Valley Medical Care as rapidly as our *actuarial experience justifies.* This is the voluntary insurance plan, initiated by the Monroe County Medical Society in 1945, for surgical and obstetrical care. We have already proposed to them a revision which calls for a service plan, with an income ceiling, to include surgical, obstetrical, and in-hospital medical care. It anticipates G.V.M.C. as a member of the newly formed regional enrollment agency which will provide universal enrollment and coverage for those firms and unions desiring blanket coverage for those firms and unions desiring blanket coverage for their employees. Plans for these improvements are going forward as rapidly as possible.

We propose that the indigent be taken care of by plans administered locally and financed locally, wherever possible.

We propose whatever extension of hospital insurance seems indicated by local needs. We propose adequate community support to the current hospital campaign which will give the area 350 additional beds and extra clinic facilities.

We propose continued growth of our Medical Service Bureau, which secures or kept medical care twenty-four hours a day for patients not able to reach their own doctor, or who have no physician of their own. This service covers Monroe County.

We admit that as in any plan involving the human element, there are a few weaknesses, and it is our purpose to remedy such deficiencies, as far as possible, believing that these can best be adjusted on the local level to meet local situations.

We should like to remind you that there is confusion in regard to the cost of hospital care and medical care, and to make it clear that the doctors have no control over hospital costs and are as concerned as the patient over the increase necessary in hospital costs. This increase is obviously due to the general increase in cost of food, help and maintenance. In the present inflationary schedules continue, temporary government subsidies to hospitals may be indicated.

We would favor legislation, State, if possible, for the care of chronically disabling diseases which cause an intolerable burden on the sufferers and their families; and the extension of grants-in-aid for the building of hospitals in communities not able to provide adequate hospital facilities, as are presently being provided in the Hill-Burton Bill.

We believe that the rapid growth of voluntary insurance plans in the last three years is conclusive evidence that private enterprise in this field is successful.

We further believe that the extension of these plans in areas lacking adequate medical care facilities, together with new hospitals, will draw physicians to these areas.—*January 27, 1949*

o standardize the thromboplastin is often not vailable, moreover, it is not justified, since here is no practical advantage in reporting the esults in terms of prothrombin time Nevertheess, if it is desired, the thromboplastin solution nay be "standardized" by altering from day to lay, if necessary, the technic of its preparation o that at all times the 100 per cent or undiluted ontrol plasma will clot in a previously selected narrow range, e g , fourteen to sixteen seconds, nd the 12 5 per cent or 20 per cent dilution of he control plasma will also clot in a previously elected narrow range, e g , thirty-five to thirtyight seconds (some workers prefer the 12 5 per ent dilution, others the 20 per cent dilution)

The diluent is usually isotonic saline, but plasma vhich has had its prothrombin removed by idsorption with barium sulfate may be used The shape of the hyperbolic prothrombin activty curve may vary depending upon which diluent s used Diluted or prothrombin-deficient plasma nust be used to standardize the thromboplastin Hurn, Barker, and Magath said, "On he basis of more than 20,000 prothrombin times n the past three years we have found that the preparation of thromboplastins which will give consistent results with normal plasmas is relatively simple, but the preparation of thromboplastins which give consistent results with prothrombin-deficient plasmas is difficult The importance of checking each new preparation of thromboplastin should be stressed Unfortunately, thromboplastins prepared in like manner do not always possess similar activity We check each fresh preparation with a previously 'standardized' thromboplastin Thromboplastin was considered to be standardized if the prothrombin time of 100 per cent normal plasma was seventeen to nineteen seconds, and the prothrombin time of the 20 per cent dilution of normal plasma was approximately thirty-five seconds "[3] (These prothrombin times are of no fundamental importance and would not necessarily be significant for any other laboratory)

The clinician may wonder how all this pertains to him After all, prothrombin determination is a laboratory procedure and presumably should be left to the laboratory technicians and directors Unfortunately, too few technicians and even directors are acquainted with the necessity and technic of "standardizing" thromboplastin if prothrombin concentration is to be correctly reported in terms of prothrombin time, nevertheless, prothrombin concentration is reported in terms of prothrombin time in many laboratories where standardization is not carried out Therefore, it becomes the responsibility of each clinician to satisfy himself either personally or by proxy that the prothrombin determination test is being performed properly if he wants to protect his patient from the insecurity of inadequate dicumarolization or the danger of excessive dicumarolization Unfortunately, few clinicians can devote the time necessary for such study It is suggested, therefore, that at least one qualified physician should be designated to supervise personally the prothrombin determination technic in every hospital laboratory and to set up a schedule for dicumarol therapy based on the prothrombin determination technic used in that laboratory

If the results are expressed in terms of prothrombin activity and if the thromboplastin used is derived from rabbit-brain, it is suggested that the prothrombin activity be maintained between 10 and 30 per cent, a range established by much experience at the Mayo Clinic [2 4] Quick stated that, on the basis of animal experiments, as well as by clinical observations, 30 per cent prothrombin activity was the critical level at which hemostasis was definitely affected, and it could be assumed to be the level below which intravascular clotting was inhibited, and the level to which prothrombin must be reduced for effective therapeutic results [5]

Prothrombin concentration may be safely expressed in terms of prothrombin time only if the technic and thromboplastin are standardized Even then, each laboratory must devise its own schedule range as a basis for adequate and safe dosage of dicumarol Dr Nelson W Barker of the Mayo Clinic writes "We used M—— thromboplastin at one time but could not make our results check with those of Dr S—— either for normal plasma or for the plasma of patients with varying degrees of prothrombin deficiency This is no criticism of Dr S——'s method but it merely shows that it is impossible to be sure that you can follow somebody else's prothrombin time schedule in seconds even though you use the same material for your thromboplastin "[6]

The clinician should be aware of the following procedures used in some hospitals First, it is incorrect and may be dangerous to express prothrombin concentration by dividing the prothrombin time of an undiluted normal control by the prothrombin time of the dicumarolized patient and multiplying by 100 per cent, e g , 15 divided by 30 multiplied by 100 per cent equals 50 per cent, or 15 divided by 45 multiplied by 100 per cent equals 33 3 per cent This is obviously incorrect since it is based on the erroneous assumption that the relationship between prothrombin time and prothrombin concentration is linear, whereas it is actually hyperbolic This method of estimating prothrombin concentration also ignores the fact that two thromboplastins

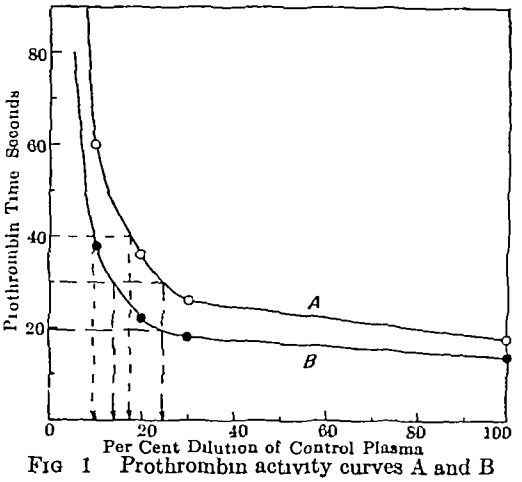

FIG 1 Prothrombin activity curves A and B

solution is less active and gives prolonged prothrombin times Third, there are differences in the concentration of the dried thromboplastin-saline suspension ranging from 2 to 10 per cent Generally, the higher the concentration, the less potent the resultant thromboplastin solution is Fourth, all dried thromboplastin extracts are contaminated more or less by clot-acceleratory and clot-inhibitory factors, whose concentration varies in different batches of thromboplastin, sometimes their concentration varies even between different portions of the same batch Consideration of the above multiple factors readily explains why thromboplastin solutions of the same potency can rarely be prepared in different laboratories, moreover, even the minute variations in procedure used by different technicians in the same laboratory may produce thromboplastins of varying potency Consequently, it is very difficult and often impossible to reproduce the same hyperbolic curve in different laboratories, or sometimes even in the same laboratory on different days It is obvious then that a "prothrombin time" range of thirty to forty seconds may indicate one range of prothrombin concentration in laboratory A on a certain day, and an entirely different range in laboratory B on the same day or in laboratory A on another day In Table 1, based on Figure 1, it is seen that a prothrombin time range of thirty to forty seconds indicates a range of 24 5 to 17 5 per cent prothrombin concentration in laboratory A, but a range of 14.0 to 9 5 per cent prothrombin concentration in laboratory B

Since "prothrombin time" frequently has no constant significance, the concept of prothrombin activity has been introduced A hyperbolic curve is constructed every day by plotting prothrombin times against the dilutions of normal control plasma, usually 100, 30, 20, and 10 per cent, which gave those prothrombin times

TABLE 1 —PROTHROMBIN ACTIVITY (CONCENTRATION) AS DETERMINED BY TWO DIFFERENT TECHNICS

Prothrombin Time Sec	Prothrombin Activity Per Cent— Technic A	Technic B
30	24 5	14 0
40	17 5	9 5

TABLE 2 —DATA ON WHICH PROTHROMBIN ACTIVITY CURVES ARE BASED

Dilution of Control Plasma Per Cent	Prothrombin Times Sec — Technic A	Technic B
100	18	14
30	26	18
20	36	22
10	60	38

(Fig 1, Table 2) (It is more accurate to u pooled, fresh, normal plasma rather than a sing plasma as the control) From this curve one ca determine what dilution of the control plasm would give the same prothrombin time as th plasma of a patient on dicumarol, this dilutio indicates the prothrombin activity of th plasma For example, if plasma X of unknow prothrombin concentration gives a prothromb time of thirty seconds using technic A, plasm X will correspond to a 24 5 per cent dilution control plasma and may be said to exhibit 24 per cent prothrombin activity If the sam plasma X were submitted to a prothrombin te using technic B, a prothrombin time of nineteen and a half seconds would be obtained (Fig 1 Thus, two different prothrombin times ma indicate the same prothrombin activity or pr thrombin concentration It can be seen readil that if a clinician wished to maintain a dicumaro ized patient in the range of 10 to 30 per cent pr thrombin activity, the prothrombin time rang would have to be twenty-six to sixty seconds f technic A but eighteen to thirty-eight second for technic B

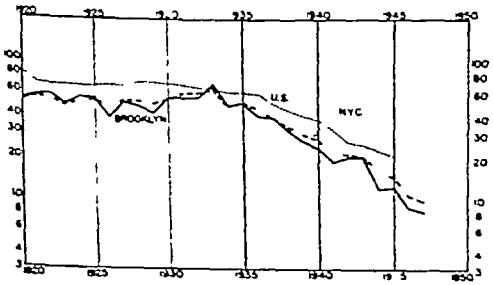
Some of the advantages of expressing pr thrombin concentration in terms of prothrombi activity rather than prothrombin time are s follows (1) The effect of the daily variation i potency of thromboplastin is practically eradicate if one is considering the results in the sam laboratory, thus one can compare with grea accuracy prothrombin concentrations reporte on different days (2) One can better, althoug not absolutely, correlate the results obtained i different laboratories, provided the same type o thromboplastin, e g , rabbit-brain or rabbit-lung is used in these laboratories

It should be pointed out that in the same labo ratory if the thromboplastin and the technic o prothrombin determination are rigidly "standardized," prothrombin time may be used as ar accurate measure of prothrombin concentration In many hospital laboratories, especially those where the staff is composed of only one or two technicians, the additional time and labor required

WHITE AND NONWHITE MATERNAL MORTALITY IN BROOKLYN, NEW YORK, 1947

CHARLES A GORDON, M D , F A C S , Brooklyn, New York

(Chairman, Brooklyn Committee on Maternal Welfare)



MATERNAL death rates continue to decline In 1946, notwithstanding a 20 per cent increase in the number of births in the United States, the number of puerperal deaths decreased 9 1 per cent with an estimated maternal mortality rate of 1 6 per 1,000 live births—a new record low [1 2] The statistics of mortality show decline in all three of the leading causes of death Considerable difference between white and nonwhite mortality risk continues Up to 1946 the nonwhite rate was more than two and one-half times as large as the rate for the white race, with greatest relative risk in toxemia

The rate for the City of New York for 1947 was 9 1 per 10,000 total births The nonwhite puerperal death rate was three times as large, and the rate for abortion seven times as large as the rate for white women The extraordinarily low maternal death rate of this great city of nearly eight million people, with a nonwhite population much larger than is indicated by the 1940 census, is a great achievement in public health

Brooklyn, with more births than any other borough and despite a record number of births in 1947, has a new low maternal death rate of 7 9 per 10,000 total births, a reduction of 9 per cent The nonwhite rate was two and one-half that of white women, and the abortion death rate was five times as great A fairly consistent parallel may be seen in the rates for the United States the City of New York, and Brooklyn over the last twenty-five years with sharper decline in Brooklyn in 1944 and 1946 (Fig 1)

PUERPERAL MORTALITY

UNITED STATES, CITY OF NEW YORK, AND BOROUGH OF BROOKLYN*

* United States Rates Per 10,000 Live Births, New York City Rates Per 10 000 Total Births, Brooklyn Rates Per 10,000 Total Births

FIG 1

In 1947, 76 women died in Brooklyn of causes associated with pregnancy and childbirth The Bureau of Records of the Department of Health City of New York assigned 58 cases to puerperal causes and 18 deaths to nonpuerperal causes, of which only cardiac disease deserves special mention

In any critical study of maternal mortality it is necessary to examine all the deaths, not only those assigned by the statistician to puerperal causes Particularly because of heart disease, the true risk of pregnancy cannot be measured otherwise Heart disease is the leading cause of death in the United States As a considerable increment of our declining maternal death rate, it grows steadily in importance As a matter of fact, its true significance has not yet been widely appreciated

In all, 15 deaths were associated with heart disease, eight deaths were assigned by the statistician directly to this cause and were not counted as maternal deaths In seven cases death was assigned to puerperal causes, yet the primary cause of death in all but one of these 15 deaths was cardiac

If we are of the opinion, and I believe we are, that a patient who has decompensated during pregnancy should not be treated at home but should be hospitalized until term, no matter how far off that may be, prenatal care was inadequate in every case but one The significant data will be found in Table 1

The official tabulation and assignment of puerperal deaths for 1947 with comparison of deaths in 1946 are shown in Table 2

Death Early in Pregnancy

Other than heart disease, death early in pregnancy was due to abortion (nine cases) and ectopic pregnancy (four cases)

The uterus was perforated in two of the four cases of induced abortion In three cases hemorrhage was profuse and was the direct cause of death in two cases, in spite of administration of large amounts of blood and plasma In one of these cases laparotomy preceded curettage, since ectopic pregnancy was suspected, in the other a four-months placenta was retained for six hours after hospitalization when severe hemorrhage occurred, followed by manual removal, 1,000 cc of plasma, 4,000 cc of blood, and finally

of significantly different potency may give similar prothrombin times on undiluted control plasma, but markedly different prothrombin times on prothrombin-deficient plasma, either diluted control plasma or dicumarolized plasma [3]

A second procedure, which is commonly utilized to estimate the therapeutic range of prothrombin concentration, is to give enough dicumarol to lengthen the prothrombin time of the patient to two to three times the prothrombin time of the control plasma In ordinary practice this is generally effective, but basically it is incorrect for the same reasons as noted above for the first procedure and may on occasion prove dangerous To illustrate, prothrombin activity curve A reveals a prothrombin time of eighteen seconds for the undiluted control, two to three times 18 gives thirty-six to fifty-four seconds which corresponds approximately to 20 to 11 5 per cent prothrombin activity (Fig 1) Prothrombin activity curve B, obviously obtained with a more potent thromboplastin than A, shows a fourteen-second prothrombin time for the undiluted control, two to three times 14 gives twenty-eight to forty-two seconds, which corresponds to a prothrombin activity range of approximately 15 to 9 0 per cent (Fig 1) Both of these ranges would be safe and effective, but with thromboplastins more active than that giving prothrombin activity curve B, a critically low range, dropping considerably below 10 per cent prothrombin concentration, would be produced with the resultant possibility of serious hemorrhage With thromboplastins much less active than that giving prothrombin activity curve A, a relatively high range of prothrombin concentration exceeding 30 per cent could result, with the resultant danger of inadequate protection from thromboembolic phenomena

A third incorrect procedure is that of testing 100, 30, 20, and 10 per cent dilutions of a patient's plasma before he receives dicumarol and using these data as the basis for a prothrombin activity curve by which future dicumarol dosage may be established for that patient This procedure is incorrect for several reasons, first, a patient with thromboembolic disease is not a valid control, second, a prothrombin activity curve based on a valid control or group of controls should be constructed every day, using the *same* thromboplastin solution with which the patient's prothrombin determination will be performed

There is considerable variability in the quantity of dicumarol required by different individuals to remain in a selected range of prothrombin activity or prothrombin time Some patients are sensitive to small doses of dicumarol, others are resistant to large doses Each patient must be treated individually One may use, however, the following schedule as a rough guide The first dose is 300 mg , thereafter, 100 to 200 mg usually the latter, are given on each day that the prothrombin activity exceeds 20 per cent I the prothrombin activity drops below 20 per cent no dicumarol is given that day If the prothrombin activity falls below 10 per cent and remain there for more than one day, 72 mg of menadion bisulfite (synthetic vitamin K) are given intravenously, and may be repeated every four t six hours if necessary If a patient is found to be resistant to dicumarol, the dose may hav to be increased to 300 mg on those days when the prothrombin activity exceeds 30 per cen If a patient is found to be sensitive to dicumaro the dose may be decreased to 50 mg on those day where the prothrombin activity exceeds 20 p cent Once again it should be emphasized th the above suggestions form only a rough guid the ability to bring the prothrombin concentration into the desired therapeutic range rapid and keep it there without excessive fluctuatio can be acquired only through experience

Summary

1 Dicumarol therapy has significantly duced the mortality and thromboembolic co plications associated with acute myocard infarction, phlebothrombosis, thrombophlebi and pulmonary embolism and infarction.

2 The administration of dicumarol in s but adequate doses depends on the proper labo tory determination of plasma prothrom concentration.

3 Plasma prothrombin concentration may expressed correctly in terms of either prothro bin activity or prothrombin time, but it is laborious, less time-consuming, and genera safer to use prothrombin activity

4 It has been emphasized that the prac of basing dicumarol dosage on various prothro bin time schedules described in the literat is incorrect and may be dangerous

5 It is suggested that at least one quali physician be designated in each hospital to sup vise the prothrombin determination tech and to set up a schedule for dicumarol ther based on the prothrombin determination tech used in the laboratory of that particular hospi

TABLE 3.—HEMORRHAGE AS THE CAUSE OF MATERNAL DEATH IN BROOKLYN 1947

Cause	Statistics	Reassignment
Abortion	9	3
Ectopic	4	4
Hemorrhage	12	12
Toxemia	11	1
Infection	10	1
Accidents	7	2
Other	5	1
Total	58	24

received neither blood nor plasma Another who died of inversion of the uterus received 250 cc of plasma, and another patient who died of postpartum hemorrhage after cesarean section received 500 cc of plasma

When hemorrhage has been profuse, administration of plasma is but a burnt offering to convention Often it is used when the still small voice within has finally been heard Although still widely used as a stopgap, use of pooled plasma implies considerable risk of homologous serum jaundice It should be discarded as dangerous

We have repeatedly shown that hemorrhage is actually the leading cause of maternal death That the situation remains unchanged will be seen in Table 3

Anesthesia

Other than in three cases following operation for ectopic pregnancy under cyclopropane, death was due to anesthesia in at least five cases and probably two more as follows *Aspiration of* vomitus during gas-oxygen-ether anesthesia (two cases), spinal anesthesia for cesarean section (one case), caudal anesthesia during low forceps delivery (one case), and cyclopropane and curare in the course of hysterectomy for retained placenta In two additional cases death occurred shortly after low forceps delivery under general anesthesia, cyclopropane and gas-oxygen-ether sequence

There is risk in allowing food to any woman once labor is established That long labor presents a food problem which may become serious is admitted Both obstetrician and anesthetist must be ever alert to the hazards of induction and emergence Anesthesia should never be crowded if the breath is held or attempts at vomiting occur When induction is complete, the anesthetic level should not be lowered until the need for anesthesia is at an end Reinduction for repair of episiotomy adds to the risk

The ease of induction and recovery appear to make cyclopropane an asset to the obstetrician, but its very potency, danger of ventricular fibrillation, and hazard of explosion should prohibit its use in other than exceptional circumstances There is evidence that the favorable attitude of many obstetricians to cyclopropane should be reviewed The risks incident to anesthesia for delivery, and particularly in the case of cyclopropane, are far greater than is generally thought

Cesarean Section

Death was associated with cesarean section in 15 cases The causes of death were postpartum hemorrhage (four cases), anesthesia (one case), eclampsia (two cases), heart disease (three cases), and infection (five cases)

The lower segment operation had been selected for all five patients who died of infection, in only one case had labor lasted as long as twelve hours Two women who were not in labor died of embolism following thrombophlebitis, one on the ninth day, on her way home from the hospital, the other on the seventh day shortly after ligation of the inferior vena cava

Year after year in Brooklyn, cesarean section has been associated with maternal death in a ratio of approximately 1 4, yet, broadly speaking, the public and, unfortunately, some of those who actually perform the operation, look upon it as a relatively easy and safe procedure Death from infection cannot always be prevented, nor from hemorrhage, but no cesarean section should be performed without 1,000 cc of suitable blood on the delivery floor Only those qualified to examine its indications, weigh the risk, and cope with the situations which may arise should perform cesarean section The decision to perform the operation is more momentous than selection of the type of operation

The Nonwhite factor

In our national statistics on maternal death, decline has been rapid and uninterrupted since 1937, yet a definite racial differential remains constant, with mortality risk for nonwhite much higher than for white women Not only that, but reduction in rates for the principal causes of maternal death is not parallel In 1945, the nonwhite rate was 4 5 or two and six-tenths times as large as the 1 7 rate for white women, this difference was maintained in the rates for infection and hemorrhage, but the rate for toxemia was three times the white rate, just as it is in the City of New York

Again in New York City the nonwhite rate for abortion is seven times the white rate, while in Brooklyn it is five times as large Even these high rates are better than those of a decade ago Trustworthy national statistics on the frequency of death from abortion are not to be had In 1940 official estimates rated abortion as contributing 30 to 35 per cent to maternal deaths from all causes

TABLE 1.—HEART DISEASE ASSOCIATED WITH PREGNANCY (PUERPERAL AND NONPUERPERAL DEATHS)

	Number of Cases	Deaths
Rheumatic—all admitted in failure	8	6 died undelivered 2 low forceps
Hypertensive	3	1 induced abortion (infection) 1 therapeutic abortion (failure) 1 admitted in failure improved died at home
Congenital—all cesarean section	4	3 died of cerebral embolism

fatal hemorrhage In another case therapeutic abortion at three months for malignant hypertension was followed by heart failure one week later In another case, since the placenta could not be expressed from a large myomatous uterus, hysterectomy was performed under cyclopropane anesthesia and curare, sudden death occurred before closure of the peritoneum

There were four operations for ectopic pregnancy, in three of which hysterectomy was performed All patients received large amounts of blood Although the peritoneal cavity was filled with blood in every case curiously enough death was not actually due to hemorrhage in any case In three cases cyclopropane anesthesia contributed to death, reported as due to widespread pulmonary atelectasis (one case), left side heart failure (one case), and prolonged pulmonary edema, clearly not of cardiac origin

Infection

There are 11 cases in this group In eight cases in which a diagnosis of septic pulmonary embolus is well supported, delivery was associated with cesarean section (three cases), low forceps (three cases), manual removal of the placenta (one case), and spontaneous delivery (one case) In five cases in which phlebitis preceded embolism, early ambulation had been practiced, in three of these cases sudden death occurred shortly after discharge from the hospital

It is good to get women up and about reasonably soon after parturition, not for prevention of embolism, but for practical reasons There can be no doubt that chemotherapy and antibiotics are largely responsible for the sharply reduced national death rate from sepsis However, this therapy is not likely to be successful in the treatment of thrombophlebitis and prevention of embolism Prophylaxis by nice technic, minimal trauma, and maintenance of high antepartum and postpartum hemoglobin levels is more helpful than therapy Every woman who dies of puerperal infection has had her chance with penicillin

TABLE 2.—PUERPERAL DEATHS—BROOKLYN 1947

Index* Rubric	Cause	1947	1946
140 141	Abortion	9	7
142	Ectopic	4	2
143 to 146	Hemorrhage	12	8
144 to 148	Toxemia	11	12
147	Infection	10	12
145 to 149	Other diseases and accidents	7	11
150	All other	5	5
	Total	58	57
	Nonpuerperal	18	15
	Rate (per 10 000 total births)**	7 9	8 7

* Manual of Joint Causes of Death, Washington D C U S Government Printing Office 1940
** Rate in 1937 was 40 7

Toxemia

With 11 cases officially assigned to toxemia, another was found in the nonpuerperal group Prenatal care was good in but four cases Cesarean section was performed in four cases, twice shortly after repeated convulsions Another patient was delivered by median forceps in the midst of eclampsia In one case hemorrhage was profuse and repeated, yet death was immediately due to eclampsia

As in cardiac disease toxemia of pregnancy is best managed in the hospital Only there can antepartum management be all that it should be It is not always possible to know when and how pregnancy should be terminated, yet danger signals may, as a rule, be easily recognized Operative procedures like midforceps and cesarean section, particularly under general anesthesia, are controllable factors of death

Hemorrhage

Other than in abortion and ectopic pregnancy, hemorrhage was the cause of death in 24 cases and a contributory cause in many others. It is often difficult to discover the incidence of hemorrhage On the certificate of death it may fail of mention or be eliminated by statistical rule Review of the case record may not be any more helpful, for death often is not simple but due to a chain of circumstances Placenta previa may be primary, yet hemorrhage may be minimal, or after formidable hemorrhage death may be immediately due to anesthesia, embolism, peritonitis, or even an eclamptic convulsion

In 13 cases death was due to postpartum hemorrhage and shock associated with cesarean section (three cases), abruptio placentae (five cases), rupture of the uterus (two cases), rupture of the vagina (one case), inversion of the uterus (one case), and version (two cases) Hysterectomy was performed in four cases, in two of which hemorrhage continued after removal of the uterus

Some patients received as much as 5,000 cc of blood, others as little as 500 cc or none at all Many were given large amounts of plasma as well One patient with rupture of the uterus

A CLINICAL STUDY OF THE EFFECT OF URECHOLINE ON PARALYTIC ILEUS AND URINARY RETENTION

RICHARD H ADLER, M D , Buffalo, New York

(From the Buffalo General Hospital)

MANY drugs have been studied in the past in an effort to find a satisfactory answer to the prevention, control, or relief of postoperative gastrointestinal and urinary distention We recently had the opportunity to test the efficiency of a drug, Urecholine, in treating these conditions occurring at the Buffalo General Hospital * This experience will be presented in the hope that others may find further value in the use of this drug

Like many other choline derivatives, Urecholine has a parasympathomimetic action It was synthesized in 1935 by Major at the suggestion of Simonart, who conceived such a drug having an action like Doryl but lacking its nicotinic-like effect ** Starr and Ferguson investigated its action in various normal and abnormal conditions and especially in postoperative urinary distention [1] It was noted to have caused a desire to void and an increase in peristalsis Its action on salivation, sweating, circulation, and heart rate was reported to be minimal

The popularity of vagotomy in the treatment of peptic ulcer recently directed attention to Urecholine in treating the atonic distended stomach occasionally seen following vagus section [2-5] A fair number of patients have responded very well to such treatment with relief of distressing symptoms Its effect upon gastrointestinal motility has been confirmed by x-ray and fluoroscopic examinations and by balloon kymograph studies [6-8] A further review of the available literature suggested that this drug might be efficacious in controlling the postoperative atonic gastrointestinal tract and urinary bladder

To test this thesis, therefore, a clinical study was undertaken In an effort to minimize the many variables in such a study, specially prepared sheets were placed on the charts of selected patients to record certain observations and reactions Urinalyses and blood counts were also followed in many individuals

We were interested to know whether the incidence of ileus and abdominal distention could be reduced if a group of postoperative patients was started on prophylactic doses of Urecholine for the first few days when compared with a similar control group not receiving the drug These patients were almost all on the surgical service All operations were performed under general or spinal anesthesia The preoperative and postoperative treatments were well standardized A determined effort was made to avoid any bias so that the undertaking would merely ascertain the facts as indicated in the final tabulations

Group I

A total of 40 patients received Urecholine prophylactically during the immediate postoperative period A similar number were checked as controls The various operations are listed in Table I

TABLE 1.—OPERATIONS ON 40 PATIENTS (URECHOLINE USED PROPHYLACTICALLY IN POSTOPERATIVE PERIOD)

Operations	Number of Cases
Cholecystectomy	8
Appendectomy	8
Inguinal herniorrhaphy	5
Ventral herniorrhaphy	2
Exploratory laparotomies	6
Pelvic operations	7
Intestinal resections	4
Total	40

Ten milligrams, three times daily, were given to those patients treated prophylactically The oral route of administration was used almost exclusively The sublingual route was tried on several occasions but was soon discontinued, since absorption was not as certain and this had no special attraction over the oral method No one received the drug subcutaneously During the last weeks of the study, several patients were given 20 mg three times daily prophylactically with no untoward effects

Whenever possible, Urecholine was started the day of surgery Occasionally the patient refused to swallow the tablets this soon, in which case the tablets were dissolved in water and so given The average length of time during which the drug was administered was four postoperative days The final tabulations are presented in Table 2

Periodic clinical observations with a comparison to the preoperative state served as the most satisfactory measure of abdominal distention. Distention was divided into two groups, mild and marked In the mild cases the distention was apparent during the first or second postoperative days, usually subsiding with the onset of peri-

* Urethane of Beta Methylcholine Chloride supplied through the courtesy of Merck & Co

** Carbaminoylcholine.

Good progress in reducing the risk of pregnancy and childbirth has been made in the City of New York for both white and nonwhite mothers, with 69 per cent decline in the white rate and 64 7 per cent reduction in the nonwhite rate from 1939 to 1947 During this same period the nonwhite rate for Brooklyn was reduced 76 per cent

This is *important, for in 1939 in the entire* City of New York the number of births to Negro women was 11 per cent of the total number of births while in 1947 this figure was 8 9 per cent In Brooklyn in 1939 the number of births to Negro women was 6 per cent of the total number of births, while in 1947 it had increased to 9 per cent The maternal mortality of the Negro has an important corollary in statistics of fetal death In Brooklyn the Negro rate of stillbirth was two and one-half that of white women

Why should the Negro maternal mortality rate continue to lag? In an excellent discussion of "Maternal Welfare and the Negro," Williams has stated the problem better than anyone else [3] The answer is not simple There are many factors in the national problem, but in Brooklyn the midwife, home delivery, and opportunity for prenatal care do not enter into the problem These women are largely delivered in hospitals with opportunity for good prenatal care, supervision of trained obstetricians, and minimal obstetric interference Greater incidence of hypertension and nephrosclerosis and their tendency to toxemia are important factors Negro women do not always make the most of prenatal care, but neither do white women It may well be that there are marked differences in the constitutional patterns of the white and Negro races.

At any rate, the nonwhite maternal mortality *rates invite our serious attention*

Conclusion

Estimates of ten years ago that the maternal death rate might be reduced as much as two thirds have proved to be sound but conservative In Brooklyn, where decline in this rate has consistently paralleled the national level, further gains may be made by special attention to the nonwhite factor and continued pressure on the primary controllable factors—abortion, hemorrhage, cesarean section, anesthesia, toxemia, and finally cardiac disease, which has been well called the fourth cause of maternal death

A NEW, SIMPLE AND QUICK PREGNANCY TEST

A new test for pregnancy which is virtually 100 per cent accurate, even shortly after conception, and which requires only a few minutes to perform, has been developed by Dr Garwood C Richardson, of Northwestern University's Medical School, in Chicago A chemical test of urine, already used on more than 1,000 cases over a five-year period, Dr Richardson's method eliminates the use of laboratory animals, such as rabbits, frogs, rats, etc. It may be made in the doctor's laboratory with simple equipment while the patient awaits results in the outer office

The Richardson test is based on the presence of a substantial amount of estrone in the patient's urine For purposes of the test, estrone in the specimen must be separated from progesterone derivatives, the presence of which *interferes* with estrone determination Reaction of the urine to sodium hydroxide and chloroform causes the desired extraction of progesterone derivatives, with the ultimate sample to be assayed rising to the top and transferring to an inner test tube for the final step in the analysis

Estrone in one procedure, causes the sample to turn brown to indicate positive results, in another, violet-red. Estrone contains a phenolic hydroxyl chemical group and is acidic enough to react with sodium hydroxide to form sodium estronate. This salt is not soluble in chloroform and hence, if the solution containing it is extracted with chloroform, sodium estronate will remain in water *solution* This solution then is caused to couple chemically with either of two reagents, each of which produces its typical color reaction diagnostic of pregnancy In the first instance, a stable brown color indicates the presence of estrone in the urine, while *in the* second, *the development of a violet-red color* is a positive sign

tention and discomfort from inability to void The following operations were included hemorrhoidectomies, fistulectomies (anal), colostomies, pelvic and abdominal laparotomies, hip nailings, herniorrhapies, laminectomies, and curettage of protruding intervertebral disks with simultaneous spinal fusions

The results of this series were the most encouraging of any in this study Forty-four per cent of these individuals were definitely benefitted by the drug and were able to void and obtain relief The use of the drug was withheld until it was obvious that catheterization was necessary Several times patients would void just before the drug was given For this reason, the patient was urged to try voiding, while out of bed or while standing, before receiving the drug After these measures had failed, the individual was given 15 mg orally If voiding did not follow within one-half hour, 20 mg were administered and one-half hour allowed to pass If there were no results, 25 mg were given, and if the patient did not void during the following one hour, catheterization was performed It soon became apparent that the third dose had very little effect when the first two had failed Therefore, the last several weeks of the study the routine was changed to 15 mg followed in one-half hour by 25 mg with catheterization one hour later if nothing occurred

About 40 per cent of the cases that voided did so after the first dose Three patients complained of cramps and a desire to void Catheterization gave them instant relief Two of these three were men known to have mild prostatic hypertrophy

Males should be checked for prostatic enlargement before administering the drug, since any evidence of a mechanical obstruction is a definite contraindication of the use of Urecholine

Discussion

Urecholine was effective in two cases where prostigmine failed, failed in a case relieved by prostigmine and in another relieved by furmethide However, no patient had any objectionable side reactions from Urecholine Variable undesirable side-effects have been encountered from use of similar medicaments

Several patients with urinary incontinence from chronic neurogenic lesions were treated with Urecholine, and, while the results were not encouraging, one woman did regain sufficient bladder tone to allow removal of an indwelling catheter

The drug was tried in two women undergoing abdominal perineal resection for carcinoma of the rectum, since these patients often have urinary retention requiring catheterization for some time postoperatively Both had indwelling catheters inserted at the time of surgery

The first case, a sixty-nine-year-old white woman, had her catheter removed on the second postoperative day at which time the drug was started orally, 20 mg three times daily She began to void soon after in progressively larger amounts and needed no further catheterization The second patient, a forty-seven-year-old white woman, obtained no relief from a similar dose of the drug during a week's trial and required continuous catheterization until the time of her discharge

Side Reactions

During this experience with Urecholine, very few undesirable side-effects and no dangerous reactions were seen Only two patients were given atropine because of untoward symptoms from the drug, and both obtained prompt relief by the subcutaneous administration of atropine sulfate $^1/_{100}$ grain This freedom from side-effects, plus the knowledge that atropine abolishes undesirable side reactions, a fact not consistent with most other parasympathetic medicaments, has allowed the use of higher dosages near the end of this study

The untoward effects were mainly abdominal cramps or discomfort associated with a desire to void Salivation and sweating occasionally were seen with larger dosages

Being a parasympathetic stimulant, Urecholine could produce bronchoconstriction as an undesirable side-effect, a serious condition in an asthmatic Therefore, all histories were checked to avoid giving the drug to a susceptible individual, with the result that this complication was not encountered

There were no remarkable changes in blood counts or urines checked during the study

The most promising therapeutic value for Urecholine would seem to be in combating acute urinary retention. The incidence of postoperative catheterization has been definitely reduced by using this drug Oral administration provides a simple and pleasant means of administration without discomfort to the patient

It is difficult to explain why some cases, theoretically ideal, failed to respond to the drug Undoubtedly a great difference in individual susceptibility and reaction existed Perhaps part of this failure may be explained on the basis of an inadequate dose in certain less responsive individuals

While the results obtained in treating the acute postoperative urinary retentions are the most encouraging, one should not discard the possibility of therapeutic benefit from Urecholine in ileus and chronic gastrointestinal or urinary

TABLE 2.—RESULTS OF POSTOPERATIVE USE OF URECHOLINE IN 40 PATIENTS

	Number	Distention		Nausea	Emesis	Urinary Retention	Hours First Voided	Postoperative First Flatus
		Mild	Marked					
Received drug prophylactically	40	5	3	8	4	6	22	42
Control patients	40	6	4	7	6	9	25	47

stalsis by the third, fourth, or fifth postoperative day Two markedly distended cases required intestinal intubation with continuous suction for relief, at which time the drug was discontinued There was no dramatic reduction in the incidence of distention in the prophylactically treated group

Cases of widespread peritonitis were not included, but an effort was made to include cases having peritoneal trauma and those necessitating considerable handling of viscera at surgery The figures in Table 2 represent nausea and emesis which occurred during the first postoperative day or later Because of anesthesia and immediate surgical trauma, it did not seem fair to include with these figures the occasional nausea and emesis seen on the day of surgery

No attempt was made to give an individual in the prophylactic group with a distended bladder an added dose of Urecholine to stimulate micturition, since this would have upset the accuracy of comparing the results of the standardized prophylactic dose Therefore, a few patients had to be catheterized who might have been stimulated to void by giving additional drug at the time of urinary retention

There was a wide range in the time of the first voluntary voiding, but the average figures in each group were not significant The time intervals for passing the first rectal flatus were even more widespread and difficult to determine

Group II

A second group included those patients who had already developed abdominal distention This was not confined to postoperative patients, the causes of paralytic (adynamic or inhibitive) ileus being so varied, it seemed reasonable to include suitable nonsurgical cases in the study

Twenty-three patients with varying degrees of abdominal distention were treated (Table 3)

The causes of the distention were numerous and included abdominal trauma, extraperitoneal and renal irritation, systemic infections, neurogenic injuries and disease of the spinal cord, and a few postoperative distentions referred for treatment

These individuals were started on 10 mg three times daily This was continued longer than one week on several occasions Those who responded to the drug started to do so soon after the first few doses Three noticed increased peristalsis within one-half hour after the first 10 mg and passed flatus rectally Two of these patients had rather typical ileus with distended, almost silent abdomens At the end of the first half hour, they were passing rectal flatus freely with moderate relief of the abdominal distention The majority, however, did not show this spectacular improvement Those with the possibility of a mechanical factor interfering with the flow of intestinal contents were not considered It would seem that, for the most part, if an individual was to respond favorably, he did so fairly early in the treatment or else not at all

Unfortunately, no case of acute gastric dilatation was encountered during the time of this study

Several noticed increased intestinal noises and slight cramps even though they actually failed to pass flatus On one occasion the insertion of a rectal tube and the giving of an enema during the drug's action produced the desired results

In animal experiments the action of acetylcholine has been shown to be enhanced when acting upon a parasympathetically denervated organ. Therefore, it seemed reasonable to assume that Urecholine, as a choline derivative might stimulate such an organ in certain neurologic conditions Several individuals with moderate intestinal distention secondary to known central nervous system (spinal cord) pathology were treated with the drug Little benefit was obtained, and further treatment was discontinued

TABLE 3.—RESULTS OF USE OF URECHOLINE IN 23 PATIENTS WITH ABDOMINAL DISTENTION

Degree of Distention	Number	Improved	Slightly Improved	Not Improved	Made Worse
Mild	15	3	2	10	0
Marked	8	2	1	5	0

Group III

This last group includes those individuals treated for bladder distention This can be further divided into two classes acute distention with inability to void postoperatively and the chronically poorly emptying bladders, not necessarily postoperative, however

Fifty-five cases received Urecholine during the immediate postoperative period for bladder dis-

THE SALT-POOR DIET

MILTON PLOTZ, M D , F A C P , Brooklyn, New York

(From the Cardiac Clinics, Bushwick and Goldwater Memorial Hospitals)

THE salt-poor diet is one of the most frequently prescribed dietary regimens used in the treatment of disease Its use has become increasingly popular since the general recognition of the fact that it is the sodium ion rather than the amount of fluid consumed which is responsible for the retention of fluid in the body The diet is of most value in the treatment of heart disease but also, although to a lesser degree, in disorders of the liver, kidney, etc It has, however, been difficult to prepare a diet acceptable to most patients, and it is the purpose of this paper to present a diet which has been used with success

There are several regimens in popular use which are as free of salt as a diet can be unless prepared in a special metabolic kitchen, but, useful as they are, their value is limited to illnesses of short duration The Karrell diet has fallen into disregard but is useful for periods of up to a week. The Schemm diet has been of great help in a few selected patients The Kempner rice diet has also been of help in many cases It has been our experience, however, that these diets are deficient for patients to be treated over long periods of time and that, the doctor's wishes notwithstanding, few patients will adhere to them for the months or years we expect them to live

An acceptable diet should be palatable, flexible, economical, and should take into account the patient's personal and racial prejudices As far as possible, food substitutes and artificial foods, long used in the preparation of diabetic diets but now falling off in popularity, should be avoided In short, the diet should approximate as far as possible the dietary routine of the patient's family and community, and be adequate in vitamins, calories, protein, fat, and satiety value

The following diet, in use in the Bushwick Hospital for the past six years, fulfills these requirements It contains not over 2 0 Gm of sodium chloride per day and should not be used when less than this amount is necessary

SALT-POOR DIET

All Foods Must Be Cooked Without Salt

Foods Allowed

Cereals

Ralston, cream of wheat, farina, oatmeal Puffed rice, puffed wheat, shredded wheat, permitted Noodles, macaroni, spaghetti, farfel, egg barley Sauces should not be used unless approved

Breads

Unsalted Uneeda biscuits, unsalted matzos specially prepared bread

Vegetables

All fresh vegetables cooked without salt Nutra diet canned vegetables permitted Avoid gas-forming vegetables (see below) Rice permitted freely

Soups

Vegetable soup prepared without salt

Meats and fish

All fresh meat and fresh fish prepared without salt Jelly may be added Avoid smoked, pickled, etc , fish and meat No canned fish

Eggs

Permitted

Meat substitutes

Pot cheese, farmer cheese, eggs prepared without salt, unsalted nuts

Desserts

Ice cream, ices, custard, jello, junket, sponge cake, applesauce, fruit, rice pudding

Fruit

All fresh or stewed fruits permitted Fruit juices permitted

Miscellaneous

Sweet butter, jelly, honey, Karo, maple syrup No molasses

Beverages

Tea, coffee, milk, cocoa, pure tomato juice, ginger ale, coca-cola, all liquids to be calculated as part of the fluid allowance if fluids are restricted Tomato juice cocktail not permitted

Do not add salt to food in cooking or at the table

Take no laxatives unless specifically permitted

Use no bicarbonate of soda, baking soda, rhubarb and soda

The only salt substitute permitted is Neocurtasal

In the absence of salt, the following condiments may be used in limited amounts to make foods more palatable Red, black, and white pepper, vinegar oil, dried mustard marjoram, sage, thyme, tarragon, allspice, paprika parsley, celery seeds, garlic, grated raw onion, sugar, horseradish (prepared at home) lemon, lime, nutmeg, mace, ginger curry, sour salt (U S P citric acid), vanilla, and other concentrated flavoring

Do not eat

1 Salt or prepared mustard
2 Smoked meat or fish
3 Any cheese except pot cheese or farmer cheese
4 Gas-forming vegetables cabbage, cauliflower, turnips, radishes, brussels sprouts, endive
5 Beer No alcohol unless prescribed

A vitamin supplement is usually added

This is *not* a salt-free diet It is relatively salt-poor and should not be used in circumstances calling for calculated diets It is, however, of great value in chronic cases in which most extremely rigid diets are eventually rejected

atony Since there is such a variance in individual response, further study and evaluation in these conditions are warranted

Summary

1 A clinical study is presented to determine the effect of oral Urecholine in treating paralytic ileus and urinary retention The cases included are grouped under three headings (1) prophylactic postoperative treatment to reduce the incidence of paralytic ileus, (2) the treatment of already established abdominal distention, and (3) the treatment of postoperative and chronic urinary retentions

2 The results in the first two groups are not impressive Definite benefit is noted in the third postoperative group, however, the results are not compared with other similar medicaments in current use

3 Urecholine is relatively free from undesirable side-effects with oral administration Untoward side-effects are promptly relieved by atropine

NEW YORK STATE MEDICAL LIBRARY

Doctors of New York State are reminded of the facilities of the State Medical Library at Albany They are invited to visit, telephone, or write to the Library where a trained staff of librarians will take care of their requests

Upon request, a copy of the regulations will be sent, which lists the services of the Library, including the compiling of bibliographies, sending material on specific subjects, or filling requests for definite book or journal references

A collection of over 57,000 books and the receipt of approximately 600 current medical journals enable the Medical Library to offer a real service to the doctors of the State

Letters may be addressed to Miss Maude E Nesbit, Librarian, New York State Medical Library, Education Building, Albany 1, New York

A MODIFICATION OF THE SLIDE Rh DETERMINATION*

IRA B COHEN, M D , and HANNAH PRETSHOLD, M S , New York City

(From the Blood Bank and Laboratory of Beth Israel Hospital)

THE etiologic importance of the Rh factor in transfusion reactions and erythroblastosis fetalis has made it essential that the Rh type as well as the conventional A-B-O groups be determined for every blood donor and potential recipient [1] Ideally, as complete a typing as is possible should be performed, but this in impractical for the ordinary hospital In difficult cases where thorough study is indicated, the Rh and Hr grouping and subgrouping can be done The other extreme of using an Rh-negative donor as a universal donor is not only wasteful but is dangerous, because an Hr negative patient can become sensitized by the Hr antigen which is always present in Rh-negative blood [2 3] Although the tests for A-B-O grouping, M-N grouping, and A_2 subgrouping are both rapid and accurate, an altogether satisfactory method for rapidly determining the Rh type has not been described [4]

Diamond and Abelson developed a slide sensitivity test for the detection of Rh antibodies using known Rh_0-positive cells [5] Unger *et al* adapted this test in the operation of blood banks to determine the presence or absence of the Rh_0 factor in the cells of prospective donors and recipients by using a testing serum containing Rh_0-blocking antibodies with oxalated whole blood as the cell suspension [2]

In this hospital we have used this technic to differentiate between Rh_0-positive and Rh_0-negative blood All specimens found to be Rh_0-negative by this method were checked by the tube agglutination technic [6]

In using the rapid slide test on oxalated blood we found that there were too many false Rh_0-negative bloods It was noted that when clotted blood was used for the slide Rh_0 test our false negative and questionable results were eliminated

Technic

The apparatus consists of a glass plate marked off into 16 squares (four horizontal and four vertical), each horizontal row being used for the complete typing of one specimen of blood The blood samples used are 50 per cent cell suspensions of both oxalated and clotted blood In specimens where the hematocrit is obviously low the blood is centrifuged, and plasma or serum is decanted to produce the optimal suspension

The tube of clotted blood is vigorously stirred with a paper drinking straw, and one small drop of blood is placed in each of the first two horizontal squares and two drops in the third square In the fourth square are placed two drops of oxalated blood To the square in the first column a drop of A (anti-B) serum is added, to the second square a drop of B (anti-A) serum is added, and to the squares in the third and fourth columns a drop of Rh_0 blocking serum is added The mixtures are stirred with separate wood applicators, and the glass plate is then placed on a viewing box containing an electric bulb under a ground glass plate The box is rocked back and forth for one to three minutes, and then the grouping tests are read The presence or absence of agglutination with the A and B serum and clumping with the Rh_0 blocking serum can be seen with the naked eye After agglutination and clumping appear to be complete, a drop of normal saline is added to each square to rule out the presence of rouleaux formation The A-B-O grouping is read in the usual manner The presence of clumping with the Rh_0 blocking serum in the absence of rouleaux formation indicates that the cells contain the Rh_0 factor [7]

Five hundred consecutive bloods were tested with the Rh_0 slide blocking serum using oxalated and clotted blood The similar results obtained in 409 cases (81 8 per cent) are recorded in Table 1

TABLE 1.—SIMILAR RESULTS OBTAINED WITH OXALATED AND CLOTTED BLOOD

	Slide Technic: Oxalated Blood	Slide Technic: Clotted Blood	Tube Agglutination Test	Number of Cases	Percentage
				301	60 2
1	+	+		14	2 8
2	−	−	+	44	8 8
3	−	−	−	31	6 2
4	++	++		9	1 8
5	+	++		5	1 0
6	+ weak	+	+	1	0 2
7	+ weak	+ weak	+	1	0 2
8	++	+ weak	+	3	0 6
9	++ strong	+			
Total				409	81 8

In 91 cases (18.2 per cent), which are tabulated in Table 2, there was a difference in the results obtained when using clotted and oxalated blood The most frequent discrepancy found was the appearance of a negative result with oxalated blood, whereas the clotted blood gave a positive result which was verified by the tube test with

* Supported by a grant from the Tillie Bloom Fellowship Fund.

The following explanatory notes regarding the details of the diet should be read carefully by the dietitian, physician, or nurse planning to use this or any other salt-poor diet

The labels on packaged foods of all sorts should be read from time to time, each time of purchase being not too often It has been found that items previously recommended on this diet have had salt added to them without notice

The admonition regarding sauces to be added to foods of the spaghetti family is important Formerly it was thought sufficient to forbid merely "spicy" sauces, the delicious sauces so often used with spaghetti It has since become obvious that cheese sauces, often substituted, contain just as much sodium chloride If sauce is desired, the patient should consult the dietitian

Unsalted Uneeda biscuits are permitted Other biscuits of similar type may be approved, but only after their composition has been definitely determined Matzos, the traditional Jewish unleavened bread, is the most popular bread substitute Its sale, formerly confined to the Easter holiday season, has become year long because of its crisp attractiveness Labels should be consulted, however, since salt is often added to the perennial variety Bread should be forbidden unless specially prepared Some patients and hospitals will prefer to bake their own bread In some communities, commercial bakeries prepare salt-free bread and cake when there is sufficient demand

Almost all vegetables are permitted and can be made palatable, even to gourmets, by judicious use of spices, lemon juice, etc Although "gas-forming" vegetables are forbidden, they may be permitted in isolated instances in which the patient demands them and finds that they do not upset his digestion

Vegetable soups are permitted In accord with the modern policy of allowing fluids more freely when the diet is low in salt, soup, formerly interdicted, is now allowed In our experience, few soups, except those prepared with mixed vegetables, are acceptable unless salt is used If the patient will take other kinds of soups, prepared without salt, he should be permitted to do so Neocurtasal will make soups acceptable

Most meats and fish are permitted, and few patients find them objectionable when prepared without salt Jellies will often take the curse off these foods, the traditional use of mint jelly with roast lamb is a good example of the acceptability of this combination Meats may be improved by the judicious use of lemon juice, onion, garlic, and the other spices mentioned

The cheeses require a word of comment Each racial group has an unsalted cheese which can be recommended safely Pot cheese (and its pressed variety, farmer cheese) can be bought in all eastern metropolitan centers, especially in Jewish districts Pot cheese is a variety of cottage cheese but, unlike the latter, has no added salt

Most desserts can be allowed Cakes, if prepared, like bread, without salt or baking soda, can be included in the diet Molasses should not be used One should insist on sweet butter

Most beverages are permitted It should be noted that restriction of fluids is not an integral feature of the diet If the clinician should wish, a note regarding such restriction may be inserted at this point Tomato juice, especially if lemon juice is added, is an excellent drink Here again, labels should be consulted since few brands do not contain sodium chloride.

The admonition regarding salt and salt substitutes is of the utmost importance Most commercial salt substitutes are prepared with sodium salt and are to be forbidden If the patient insists on adding something with a salty flavor to food, a mixture consisting of equal parts of potassium chloride and finely divided starch may be used in a salt shaker The mixture should be added to food at the table, it should not be used in the preparation of food A commercial powder, made of toasted yeast (Baken-Yeast) is also found agreeable by many patients. The only permissible salt substitute is Neocurtasal, which does not contain the sodium ion.

Bicarbonate of soda, known as baking soda to most laymen, should be forbidden The alert physician should also advise against the use of rhubarb and soda or other mixtures containing bicarbonate of soda Many of the "antacids" and saline laxatives contain huge amounts of salts with sodium radicals Nearly all the naturally carbonated waters, and some of those artificially carbonated, contain considerable quantities of sodium salts, even sodium chloride.

A new feature of this diet and one considerably enhancing its usefulness is the inclusion of the condiment list When the condiments do not have added salt, they are entirely satisfactory from a medical point of view and add immeasurably to the palatability of the patient's meals At first, there was some misgiving about the possibility of their increasing the patient's thirst, fortunately unwarranted, and we have been allowing patients more fluids than formerly

Beer should be denied the patient, but other alcoholic drinks may be permitted, even prescribed, under certain circumstances Of course, there should be a warning against the use of sparkling waters in highballs and mixed drinks

Conclusions

1 A new, workable, salt-poor diet is prescribed

2 Palatability is stressed A feature is the recommendation of condiments to add flavor

PULMONARY COCCIDIOIDOMYCOSIS

FREDERIC W HOLCOMB, M D , F A C P , Kingston, New York

(From the Kingston and Ulster County Tuberculosis Hospitals)

PRIMARY pulmonary coccidioidomycosis, which has been termed "San Joaquin Valley Fever" or "Desert Fever," is caused by the fungus Coccidioides immitis and is carried into the lungs by inhalation of dust contaminated by the spores of these saprophytic organisms Prior to 1941 it was rarely encountered east of the Mississippi River, although it has been endemic in the desert regions of the Southwest for many years Up to 1931 only two cases had been reported in the eastern United States In 1892 coccidioidal granuloma was first described by Wernicke, and since that time subsequent investigations show that it is characterized by extrapulmonary or cutaneous lesions resembling erythema nodosum and pulmonary lesions which may be bronchopneumonic on x-ray appearance and which may later undergo necrosis, resulting in cavity formation Later, productive or fibrotic tissue proliferation may ensue The disseminated type of coccidioidomycosis is probably caused by hematogenous or lymphatic dissemination of the initial or pulmonary infections to other organs of the body

The training of large numbers of Army personnel for desert warfare in the southwestern United States where the climate and terrain of certain parts of California, Arizona, and New Mexico were adapted to this training created a problem in the dissemination of coccidioidomycosis Up to this time a comprehensive survey has not been made, but it has been estimated that about 6,000 cases occurred in the military personnel This group comprised men from all parts of the United States who have since been returned to their homes and may present problems in diagnosis and care in the future

This discussion is concerned with three cases, discovered in Ulster County in 1944, which presented pulmonary lesions of coccidioidomycosis My purpose in presenting these cases is to call attention to the close resemblance to cases of pulmonary tuberculosis in the x-ray findings, the clinical course, and the complications The types of these lesions vary and conform to the common typical productive or fibrotic lesion with cavity formation, the solitary cavity noted in the parenchyma of the midlung field without any considerable surrounding zone of inflammation, or the extensive bronchopneumonic infiltration with disseminated miliary nodules which may closely simulate the x-ray finding of acute miliary or hematogenous tuberculosis

The diagnosis of pulmonary coccidioidomycosis may be made by the discovery of the Coccidioides immitis in the sputum or smear This procedure, however, is very often negative, and in our cases the fungus could not be found The coccidioidin intradermal test, when positive, indicates infection, although the disease may be present in cases whose reaction is negative One-tenth cubic centimeter coccidioidin, dilution of 1 1,000 and 1 100, is injected intradermally, and reaction of 5 mm or more, which is best read at the end of forty-eight hours, can be considered positive Serial x-ray films are very essential in the diagnosis and subsequent observation of these cases

The usual symptoms are thoracic pain, irritative or slightly productive cough, fever which may be variable in both its severity and its occurrence, and hemoptysis together with the usual manifestations of a systemic infection

Treatment follows rather closely the usual procedures used in the care of pulmonary tuberculosis and its complications Bed rest with high caloric diet and the use of analgesics for the relief of pain are indicated Potassium iodide, 40 to 60 Gm daily, might be tried, although the therapeutic value is conjectural Thoracentesis may be necessary for relief of extensive pleural effusions with its accompanying dyspnea Artificial pneumothorax may be indicated for control of repeated or severe pulmonary hemorrhages

Case Reports

Case 1—This patient was x-rayed following a slight hemoptysis, and an apical productive infiltration was found in the left supraclavicular region. A radiolucent configuration was present suggesting a small cavity He had served in the Army and had had training in the southwestern desert country for several weeks He complained of small recurrent pulmonary hemorrhages and was subsequently hospitalized several times over a period of one year He received conservative treatment with bed rest His sputum and gastric contents on all examinations were negative for tuberculous bacilli, but intradermal tests with coccidioidin were positive on dilution 1 100 After one year a very severe pulmonary hemorrhage occurred, and it was considered necessary to induce left pneumothorax for about six months The lung was then allowed to re-expand He has had no episodes of hemoptysis for several months

Presented at a meeting of the Fourth District Branch of the Medical Society of the State of New York, September 25 1948

TABLE 2.—DIFFERENT RESULTS OBTAINED WITH OXALATED AND CLOTTED BLOOD

	Slide Technic: Oxalated Blood	Slide Technic: Clotted Blood	Tube Agglutination Test	Number of Cases	Percentage
1	–	+	+	45	3 0
2	–	+ weak	+	5	1 0
3	–	++	++	27	5 4
4	+ weak	++ strong	++	11	2 2
5	+ weak	–	–	2	0 4
6	Heavy rouleaux even with saline	–	–	1	0 2
Total				91	18 2

Rh_0 agglutinating serum This occurred in 77 cases (15 4 per cent, 1–3 in Table 2) In 11 cases (2 2 per cent, 4 in Table 2) the slide test with oxalated blood was weakly positive, while the slide test with clotted blood and the tube test were strongly positive In two cases the oxalated blood was weakly positive, while the clotted blood gave a negative result confirmed by the tube test In one case there was heavy rouleaux formation with oxalated blood which did not disappear with the addition of saline, the slide test with clotted blood and the tube determination were negative In 14 cases (2 8 per cent) both slide tests with oxalated and clotted bloods were negative whereas the tube determinations were positive (2 in Table 1) In general, where both clotted and oxalated bloods gave positive slide tests, the test with the clotted blood was easier to read

Discussion

Diamond and Abelson advocated the use of oxalated blood in the rapid slide technic, in order to remove fibrin, this apparently being the main reason for their choice [5] In our experience, the use of blood which has been allowed to clot completely, will eliminate any fibrin film from the slide Clotted blood has the advantage over oxalated blood in that it can be kept for two weeks at refrigerator temperature, whereas oxalated blood is good for only five days under similar conditions Also, clotted blood, if shipped by mail to a laboratory, is likely to arrive in better condition than oxalated blood [8] Another disadvantage in the use of oxalated blood is that the tubes usually contain enough potassium oxalate for 5 to 12 cc of blood, whereas in some cases where venipuncture is difficult 1 or 2 cc of blood is put into the oxalate tube We find that in these cases the slide Rh_0 determination with oxalated blood is very likely to give a false negative result

Conclusions

1 A rapid slide technic using Rh_0-blocking serum and clotted blood has been described

2 The use of clotted blood for this test has been found to be more satisfactory than oxalated blood In 500 cases there were 91 instances (18.2 per cent) in which there was a discrepancy between the results obtained with oxalated and clotted blood In each case the slide test with clotted blood was confirmed by the tube agglutination technic The most common inconsistency found was a false negative result with the oxalated blood

3 In most cases the slide test with clotted blood was easier to read than the test with oxalated blood

POLITICAL APPROACH

Dr R B Robins, Democratic National Committeeman for Arkansas, has sent the following telegram addressed to Senator McGrath

As Democratic National Committeeman for the state of Arkansas, and as a member of the House of Delegates of the American Medical Association, I wish to register vigorous protest against your misuse of the facilities of the Democratic National Committee to attack the medical profession

According to Press Association reports, your scurrilous statement of Monday, March 21, attacking state medical societies and the American Medical Association as "a medical dictatorship," was distributed by the Democratic National Committee and you were quoted as the party's National Chairman

The medical profession is threatened with a government dictatorship, not a medical dictatorship, as you well know, and your action affords eloquent evidence of why we don't want political medicine in this country

There are thousands of doctors like myself, who are Democrats in good standing, and who will resent your use of Democratic Party facilities to undermine public confidence in the medical profession. If you insist on playing politics with the health needs of the American people, you will bring discredit on both yourself and our party —*March 26, 1949*

PULMONARY COCCIDIOIDOMYCOSIS

FREDERIC W HOLCOMB, M D , F A C P , Kingston, New York

(From the Kingston and Ulster County Tuberculosis Hospitals)

PRIMARY pulmonary coccidioidomycosis, which has been termed "San Joaquin Valley Fever" or "Desert Fever," is caused by the fungus Coccidioides immitis and is carried into the lungs by inhalation of dust contaminated by the spores of these saprophytic organisms Prior to 1941 it was rarely encountered east of the Mississippi River, although it has been endemic in the desert regions of the Southwest for many years Up to 1931 only two cases had been reported in the eastern United States In 1892 coccidioidal granuloma was first described by Wernicke, and since that time subsequent investigations show that it is characterized by extrapulmonary or cutaneous lesions resembling erythema nodosum and pulmonary lesions which may be bronchopneumonic on x-ray appearance and which may later undergo necrosis, resulting in cavity formation. Later, productive or fibrotic tissue proliferation may ensue The disseminated type of coccidioidomycosis is probably caused by hematogenous or lymphatic dissemination of the initial or pulmonary infections to other organs of the body

The training of large numbers of Army personnel for desert warfare in the southwestern United States where the climate and terrain of certain parts of California, Arizona, and New Mexico were adapted to this training created a problem in the dissemination of coccidioidomycosis Up to this time a comprehensive survey has not been made, but it has been estimated that about 6,000 cases occurred in the military personnel This group comprised men from all parts of the United States who have since been returned to their homes and may present problems in diagnosis and care in the future

This discussion is concerned with three cases, discovered in Ulster County in 1944, which presented pulmonary lesions of coccidioidomycosis My purpose in presenting these cases is to call attention to the close resemblance to cases of pulmonary tuberculosis in the x-ray findings, the clinical course, and the complications The types of these lesions vary and conform to the common apical productive or fibrotic lesion with cavity formation, the solitary cavity noted in the parenchyma of the midlung field without any considerable surrounding zone of inflammation, or the extensive bronchopneumonic infiltration with disseminated miliary nodules which may closely simulate the x-ray finding of acute miliary or hematogenous tuberculosis

The diagnosis of pulmonary coccidioidomycosis may be made by the discovery of the Coccidioides immitis in the sputum or smear This procedure, however, is very often negative, and in our cases the fungus could not be found The coccidioidin intradermal test, when positive, indicates infection, although the disease may be present in cases whose reaction is negative One-tenth cubic centimeter coccidioidin, dilution of 1 1,000 and 1 100, is injected intradermally, and reaction of 5 mm or more, which is best read at the end of forty-eight hours, can be considered positive Serial x-ray films are very essential in the diagnosis and subsequent observation of these cases

The usual symptoms are thoracic pain, irritative or slightly productive cough, fever which may be variable in both its severity and its occurrence, and hemoptysis together with the usual manifestations of a systemic infection

Treatment follows rather closely the usual procedures used in the care of pulmonary tuberculosis and its complications Bed rest with high caloric diet and the use of analgesics for the relief of pain are indicated Potassium iodide, 40 to 60 Gm daily, might be tried, although the therapeutic value is conjectural Thoracentesis may be necessary for relief of extensive pleural effusions with its accompanying dyspnea Artificial pneumothorax may be indicated for control of repeated or severe pulmonary hemorrhages

Case Reports

Case 1 —This patient was x-rayed following a slight hemoptysis, and an apical productive infiltration was found in the left supraclavicular region A radiolucent configuration was present suggesting a small cavity He had served in the Army and had had training in the southwestern desert country for several weeks He complained of small recurrent pulmonary hemorrhages and was subsequently hospitalized several times over a period of one year He received conservative treatment with bed rest His sputum and gastric contents on all examinations were negative for tuberculous bacilli, but intradermal tests with coccidioidin were positive on dilution 1 100 After one year a very severe pulmonary hemorrhage occurred, and it was considered necessary to induce left pneumothorax for about six months The lung was then allowed to re-expand He has had no episodes of hemoptysis for several months

Presented at a meeting of the Fourth District Branch of the Medical Society of the State of New York, September 25 1948

Case 2—During a routine pre-employment examination of a robust individual weighing over 190 pounds and apparently in excellent health, an annular configuration was noted on fluoroscopic examination in the left midlung field An x-ray film revealed what appeared to be a thin-walled cavity about 3 cm. in diameter This patient had complained of intermittent cough with occasional blood-tinged sputum. He was later accepted for employment as a lineman with a public utility company and carried on fairly heavy work for several months About a year later he reported to the hospital complaining of marked dyspnea on exertion. Fluoroscopic examination revealed a rather dense opacity overlying the lower three fourths of the left lung field About 1,600 cc of clear, straw-colored pleural effusion was removed, and intradermal tests with coccidioidin were faintly positive on the 1 1,000 dilution and definitely positive on the 1 100 dilution. Seven days later he returned to work This episode occurred about two years ago, and he has continued his work ever since

Case 3—This patient was admitted to the hospital on June 28, 1946 He gave a history of an acute pulmonary infection which began about June 25 His temperature on admission was 104 F with 23,000 white blood cells and 70 per cent polymorphonuclear leukocytes. There was considerable cyanosis, and his respirations were 45 per minute and rather shallow His cough was nonproductive in type, but x-ray films on admission showed an extensive bilateral involvement of both lung fields with miliary nodules which suggested a miliary tuberculosis The film of July 3 showed a more sharply defined miliary nodulation with two small circumscribed shadows in the first interspace anteriorly which suggested beginning cavity formation Streptomycin was not readily available at that time, and penicillin therapy was instituted. The patient became rapidly worse, and his cyanosis was more pronounced A spinal tap, done on admission, did not reveal any significant findings regarding increased pressure The protein was negative, sugar 86 mg per cent, and no white blood cells were found The smear showed no cells or organisms, and the cultures showed no growth in seventy-two hours Guinea pig inoculation was negative for tuberculous lesions at the end of ten weeks

To our surprise this patient began to show improvement on the twelfth day following admission Up to this time he had been somnolent and delirious much of the time His condition continued to improve, and the x-ray films showed progressive clearing after the third week. His last film of April 1, 1947, showed only a few productive strands in the upper left lung field, while the right lung field was essentially clear On September 27 coccidioidin was injected intradermally and was strongly positive with reddening and induration on dilution of 1 100 The dilution of 1 1,000 was negative This case was diagnosed as a pulmonary coccidioidomycosis. One interesting fact in this patient's history is that he served three weeks in the Arizona desert in May, 1943, and coccidioidomycosis was not manifest for over three years

These cases varied in their clinical course and x-ray findings, and each one developed complications commonly found in pulmonary tuberculosis

These cases have been examined by the U S Army Medical Department, and the diagnosis of coccidioidomycosis has been confirmed The cases are classified as "service-connected"

Summary

1 In members of the military personnel who have seen service in the desert country of the Southwest, in individuals who have visited these areas in whom x-ray studies reveal pulmonary lesions resembling tuberculosis, and when the sputum and gastric contents are negative for tubercle bacilli on smear concentration and culture, intradermal tests with coccidioidin should be made

2 Primary pulmonary coccidioidomycosis often closely simulates pulmonary tuberculosis in its clinical course, its complications, and in its serial x-ray films

3 Prompt differentiation should be made in these cases in order to avoid prolonged hospitalizations in tuberculosis sanitaria where there may be danger of adding a superimposed pulmonary tuberculosis to their existing coccidioidal disease

188 FAIR STREET

HOOVER IN WARNING ON MORE SPENDING

Former President Herbert Hoover declared recently that if we are to survive as a nation, taxes and our expenditure budget must not be increased until the cold war is won Today our Government is spending dangerously $23,000,000,000 of our expenditures of the $45,000,000,000 of the budget for the cold war He added that billions of additional expenditures were being urged upon Congress by groups and sections in the country for special projects which may be worthy but highly unadvisable at the present time

Concerning Federal medical expenses, Hoover said the Government is needlessly enlarging its hospital system at a cost up to 50 per cent more than private hospitals. He labeled medical expenditures as one of the worst overlaps, wastes and inefficiencies in the whole Federal administration

Hoover charged that the Government has 70,000 empty beds in its hospitals but is planning 50,000 more A commission survey, he said, led President Truman to suspend $400,000,000 worth of new hospital construction already authorized

He urged a United Medical Administration to coordinate five different Federal hospital services—Army, Navy, Veterans, Public Health, and aid to private hospitals—*New York Sun, April 23, 1949*

THE INCIDENCE OF MULTIPLE PRIMARY MALIGNANT TUMORS AND A REPORT OF A CASE WITH THREE PRIMARY CARCINOMATA

DAVID M SPAIN, M D , New York City

(From the Pathology Laboratories, Bellevue Hospital)

ANY report on the subject of multiple primary malignant tumors might well start with the following excerpt from the exhaustive report on this subject by Warren and Gates in 1932 "Only that person whose experience with malignant disease is limited is now thrilled by encountering a case However, the frequency or the infrequency of occurrence of these multiple tumors has great significancet for we should be able to obtain from the state of this condition light on the resistance or susceptibility to cancer as well as some clue as to the role of heredity "[1]

One of the facts used to support the mutation theory of the development of cancer is that the incidence of multiple malignant tumors is stated to be higher than would be expected if only chance were involved Warren and Gates found 40 cases of multiple malignant tumors in 1,078 postmortem examinations on patients with malignant tumors This was a 3 7 per cent incidence, as compared with the combined reports of all American observers that gave an incidence of 3 9 per cent Since 1932, the mutation theory has gained in popularity in some quarters, and it has become of interest to note whether the incidence reported in 1932 is essentially the same after a fifteen-year interval With this in mind, 5,000 consecutive postmortem examinations performed between 1941 and 1948 at Bellevue Hospital were analyzed These data must be viewed with the knowledge that skin tumors are usually not seen at postmortem examination at Bellevue Hospital and that many of the cases with breast, uterine, cervical, and gastrointestinal carcinomata that have received surgical treatment are very often not autopsied because there is little incentive on the part of the interns for securing consent in these cases These figures are, therefore, minimal figures, and probably a slightly higher tumor incidence would be correct There were 690 cases with malignant tumors Of these, 22 (3 2 per cent) had multiple primary malignant tumors (Table 1) It is interesting to note that in 115,813 postmortems collected in a review of the literature by Warren there were 15,988 with one or more malignant tumors (13.8 per cent) At Bellevue Hospital the postmortem incidence of malignant tumors in a series studied fifteen years later was also 13 8 per cent (Table 2)

As stated previously, multiple primary malignant tumors that arise in the same individual are not rare However, the majority of cases are examples of multiple tumors of the same system or organ, particularly of the skin or alimentary tract Moreover, in many of these cases the tumors appear at different periods rather than all occurring simultaneously In Warren's report that included an extensive review of the literature, there were only three cases of triple primary carcinomata that originated in three different organs These were as follows (1) bronchus, prostate, and gallbladder, (2) stomach, tongue, and adrenal, and (3) breast, stomach, and ovaries The following is a brief case report in which

TABLE 1 —INCIDENCE OF MULTIPLE MALIGNANT TUMORS

Number of postmortem examinations	5 000
Number of malignant tumors	69
Number with two primary malignant tumors	20
Number with three primary malignant tumors	2

TABLE 2 —TABULATION OF CASES WITH MULTIPLE MALIGNANT TUMORS

Age	Sex	Types of Tumors

FIG 1 Photomicrograph (hematoxylin-eosin) showing nests of atypical squamous cell in bronchus

primary carcinomata were present in the pancreas, prostate, and bronchus

Case Report

The patient, a sixty-year-old white man, was under treatment in the Outpatient Department Clinic of the First Medical Division of Bellevue Hospital The diagnosis at that time was hypertensive heart disease and varicose veins of the lower extremities There were no other complaints On August 23 1945, the patient was admitted to Bellevue Hospital in a stuporous condition after his wife had found him on the floor of his bedroom in a state of collapse No further history was obtained Physical examination disclosed a stuporous male with a left-sided hemiplegia Aside from a blood pressure of 170/110, there were no other significant findings He expired twenty-four hours later The clinical diagnoses were cerebrovascular accident and hypertensive cardiovascular disease

Necropsy Report.—Postmortem examination showed a cerebral hemorrhage (right frontal lobe), arteriolar nephrosclerosis, and a hypertrophy of the heart (The remainder of the description of the postmortem findings will be limited to the three malignant tumors)

The left upper lobe bronchus was partially stenosed by a mass of firm white tissue that was 3 cm. in diameter The mass infiltrated beyond the bronchus into the lung parenchyma. The adjacent lymph nodes were moderately enlarged and contained similar tissue Histologic section of these areas showed numerous nests of atypical squamous cells in which there was considerable keratin formation The bronchial mucosa was replaced by these cells, and the entire thickness of the bronchial wall was infiltrated The lymph nodes contained similar cells *Diagnosis* squamous cell carcinoma of the right upper lobe bronchus (Fig 1)

The pancreas was not increased in size In the tail, the normal pink lobulated architecture was replaced by a 2 5 cm. mass of firm white tissue that had infiltrated into the surrounding tissue Histologic section taken from this mass showed many acini lined with atypical columnar cells in which the nuclei had lost their polarity and were hyperchromatic and irregular in shape Many of these atypical cells had invaded into the surrounding pancreatic tissue *Diagnosis* adenocarcinoma of the tail of the pancreas (Fig 2)

The prostate was normal in size. Except for a few small nodules, it appeared relatively normal. Histologic sections of the prostate showed that several of these nodules consisted of atypical epithelial cells that had formed solid nests of cells filling the acini.

FIG 2 Photomicrograph (hematoxylin-eosin) showing adenocarcinoma of pancreas

FIG 3 Photomicrograph (hematoxylin-eosin) showing carcinoma of prostate with carcinoma cells in perineural lymphatics

There were solid cords and strands of these cells in the adjacent parenchyma The perineural and perivascular lymphatic vessels were filled with these cells *Diagnosis* carcinoma of prostate (Fig 3)

Discussion

The criteria originally established for the diagnosis of multiple distinct primary malignant tumors were that the various tumors must have distinct gross points of origin, that they must be histologically different, and that each tumor must have its own metastases

In recent years the three criteria have been modified to the extent that metastases as one of the criteria has been replaced by the requirement that the signs of malignancy must be unmistakable, as, for instance, infiltration into the surrounding tissue In this case all of these criteria were fulfilled The bronchial tumor was squamous cell in type, the pancreatic tumor was glandular, and the prostatic tumor consisted of small undifferentiated cells The bronchial tumor had infiltrated beyond the cartilage and had metastasized to the regional lymph nodes The pancreatic tumor had invaded the surrounding parenchyma and was unencapsulated The prostatic tumor had spread into the perineural and perivascular lymphatic vessels All three had distinct gross points of origin It is a point of additional interest that all three were present simultaneously and had not produced, as far as was known, any subjective clinical manifestations

Summary and Conclusions

1 The incidence of multiple malignant tumors in 690 postmortem examinations on cases with malignant tumors was 3 2 per cent This is in agreement with the incidence of 3 7 per cent recorded by Warren in 1932

2 The incidence of single malignant tumors in 5,000 consecutive postmortem examinations was 13 8 per cent This is the identical incidence obtained fifteen years ago in an exhaustive analysis of 115,813 autopsies

3 The high incidence of multiple malignant tumors would tend to support the mutation theory of the origin of cancer

4 An additional case of three distinct primary carcinomata arising in three distinct organs (bronchus, pancreas, and prostate) is presented

LUMBAR SYMPATHECTOMY PERFORMED ON THE KING

The King has undergone the operation of lumbar sympathectomy by Dr J R. Learmonth, professor of surgery at the University of Edinburgh, assisted by Dr J Paterson Ross professor of surgery at the University of London. The operation was without incident The King has for some months been under the medical treatment of a corps of specialists for difficulties in the circulation in the legs due to arterial troubles. In the left leg the flow of blood has been restored in the main arteries to a satisfactory degree But in the right leg the main artery is still obstructed and the circulation is still less efficient than in the left through a collateral circulation. With a view to improving the circulation in the right foot, right lumbar sympathectomy has been performed — *J.A.M.A., April 23, 1949*

Case Reports

PRIMARY FIBROSARCOMA OF THE HEART WITH METASTASES

HARRY COHEN, M D , Bronx, New York

(From the Lebanon Hospital)

ALTHOUGH primary tumor of the heart is rare in the experience of any one pathologic laboratory, the total number of cases recorded in the literature forms an impressive collection. However, as noted by Wall and Vichery, primary tumor of the heart with distant metastases is particularly rare [1] Wartman and Hellerstein, in their report of heart disease in *2,000 consecutive autopsies, state that* they found 16 cases of neoplasm of which one was a primary leiomyosarcoma of the right atrium with direct extension into the superior vena cava, left subclavian vein, and myocardium of the right ventricle and left atrium.[2] Metastases were also found in the lungs and adrenals

It is of great interest that the diagnosis is rarely made antemortem, *although there are three established* cases of primary intracardiac tumor that were recognized prior to death These cases were reported by Popp, Barnes *et al*, and Shelburne [3-5] In the opinion of the observers cited, there are certain suggestive or diagnostic features of a tumor of the heart

1 Unexplained and intractable cardiac failure which is *often the first and last episode of decompensation*

2 Unexplained and sometimes inconstant changes in cardiac rhythm, sounds, and size, as judged by physical, roentgen, and electrocardiographic examinations

3 Development of a hemorrhagic pericardial effusion (Tumor cells in fluid confirm the diagnosis)

4. Unexplained signs of obstruction of cardiac flow or of the blood flow of the major thoracic vessels.

5 A specimen removed in arterial embolectomy which is shown on microscopic examination to be derived from a tumor of the heart

Case Report

Patient C G , an obese white woman, age thirty, gravida 0, Para 0, was first seen April 1, 1947, complaining of cough, sore throat, and elevated temperature Her past history and family history were entirely noncontributory Patient responded to antipyretic medication and bed rest The temperature again became elevated within a few days, and the patient complained of chills and fever, cough, pain in the left chest, and bloody sputum Physical examination revealed dullness, moist rales, and bronchovesicular breathing in the right lower lobe posteriorly The patient refused hospitalization, and treatment was instituted at home with daily intramuscular injections of 300,000 units penicillin in oil and wax and oral sulfadiazine with sodium bicarbonate After six days, the chest signs resolved, but the temperature did not return completely to normal. The patient was convinced that she should be hospitalized for a more complete study and necessary therapy

The patient was not seen again for several days until she was hospitalized on May 2, 1947 At this time the patient was cyanotic but not dyspneic Physical examination of the chest revealed evidence of bilateral pleural effusion posteriorly, the heart sounds were muffled and distant but regular in rhythm. The blood pressure was 105/80 Although a pericardial effusion was suspected clinically, the roentgenologist did not corroborate the clinical impression. There was no evidence of ascites or peripheral edema. The temperature was 102 4 F , pulse 120, and respirations 20

The clinical impression was bilateral pleural effusion and pericarditis with effusion possibly on a rheumatic basis with *panserositis*

Laboratory data were as follows hemoglobin 81 per cent, red blood cells 4,200,000, white blood cells 8,600, polymorphonuclears 68, lymphocytes 27, eosinophils 2, and monocytes 3 Urinalysis was acid with a specific gravity of 1 023, clear yellow, *1 plus albumin, sugar negative, and microscopic* negative Blood culture was negative after four days Sputum was negative for tubercle bacilli Also negative were the heterophil reaction and the Mantoux test Sedimentation rate was 8 mm. per hour (Westergren)

Chest x-rays showed "bilateral pleural effusions, cardiac contours not distinguished from adjacent shadows Trachea in the midline" Electrocardiogram report was "QRS complexes of very low voltage in all leads and slurred T moderately low voltage, T_2 and T_4 isoelectric and T_3 inverted Impression myocardial damage and poor function with the marked changes probably due to pericardial effusion with poor circulation."

The patient's general condition remained unimproved, the cyanosis was present almost constantly The blood pressure ranged from 110/70 to 84/70, and the respirations from 15 to 30 per minute, the temperature fluctuating between 99 and 103 F The patient could not tolerate

salicylates, and, with no response to penicillin, therapy was changed to streptomycin In addition, intramuscular liver was given twice a week and B-complex daily

On May 8, 1947, chest x-ray was reported as showing "little change at bases of lungs The heart is enlarged to the right and left Impression pleural effusions and cardiac enlargement" On May 14, an attempt was made to do bilateral thoracocentesis, but only several cubic centimeters of what appeared to be blood was obtained The following day further x-ray of the chest was reported as "showing blunting of both costophrenic bases, less than previously reported The heart is enlarged to the left and right Impression resolving bilateral pleural effusion. Cardiac enlargement"

The patient had repeated blood counts and urinanalyses with no important changes until May 15, when the blood count revealed a moderate anemia of hemoglobin 62 per cent, red blood cells 3,560,000, white blood cells 12,800 with a differential of polymorphonuclears 75, lymphocytes 21, eosinophils 1, and monocytes 3 In view of the anemia, it was decided to give 500 cc of whole blood transfusion. The patient was typed and found to be group A, Rh positive On May 17, a citrated transfusion was started very slowly, and, after 150 cc were given, the patient suddenly had a severe reaction with a chill, marked cyanosis, and dyspnea. The transfusion was immediately discontinued, and the patient was given adrenalin and oxygen. The patient was again typed and found to be group A, Rh positive and compatible with the blood given although it was O blood. The same day the patient was transferred to Lebanon Hospital where she was immediately placed on the critical list She now showed marked cyanosis especially of the head and neck, severe orthopnea, and markedly distended neck veins on lying flat The blood pressure was 90/70, and the heart sounds were found to be distant and muffled but regular Pulse was very shallow and of poor quality

Soon after admission, an x-ray of the chest was reported as showing "marked enlargement of the cardiac shadow to the left and right in a symmetric manner The cardiodiaphragmatic angle is obtuse and suggestive of a large pericardial effusion. Whether the heart is enlarged cannot be determined."

That night, because of the critical tamponading of the heart, a pericardial paracentesis was performed through the anterior route, and 200 cc of bloody fluid were removed which did not clot on standing There was immediate improvement in the orthopnea and cyanosis, the neck veins markedly diminished in their distention, and the blood pressure rose to 120/80 However, the patient's general condition was still critical, and she was given oxygen constantly, and salicylates which were not tolerated. Because of the bloody pericardial effusion, a diagnosis of malignancy was now entertained

Another chest x-ray on May 23 was reported as revealing "a moderate left pleural effusion with marked decrease in the amount of fluid in the pericardial sac" Accordingly, on May 24, a left thoracentesis was performed and 1,050 cc of bloody fluid were removed which did not clot on standing

The fluid from the pericardial sac and pleural cavity failed to reveal any organisms or malignant cells

The patient's course was continuously downhill, and she expired on May 27, 1947

Postmortem Examination.—The organs were removed through a thoracoabdominal incision. The pleural and pericardial cavities were filled with a bloody fluid The peritoneal cavity contained about 500 cc of serosanguinous fluid The heart weighed 375 Gm The right auricle was the seat of a large, hemorrhagic, nodular, hard neoplasm the size of a baseball, which invaded the entire auricle to the subendocardium and extended posteriorly to the esophagus The mass extended in grapelike, hemorrhagic clusters around the epicardium and had several implantations on the pericardium. All the chambers of the heart were within normal limits, except the right auricle, which was narrowed by the tumor invasion The remainder of the heart was essentially negative

On frozen section, the tumor revealed fibrosarcoma Microscopic sections confirmed this diagnosis, revealing spindle-shaped cells varying in size, shape, and staining reaction Mitoses were evident Areas of necrosis and hemorrhage were seen Tumor giant cells were present

The spleen was enlarged, congested, and soft and showed a metastatic growth measuring about 25 mm. in its greatest diameter This was confirmed by microscopic study

The lungs weighed 1,200 Gm The bronchial tree appeared normal, and the lungs showed several infarcts, each measuring a few centimeters in dimension

On microscopic section the right lung revealed masses of infiltrating tumor and atelectasis

The other organs were essentially negative

Anatomic diagnoses were (1) fibrosarcoma, right auricle, with metastases to epicardium and pericardium and to spleen and right lung and adjacent lymph nodes, (2) cardiac tamponade, massive pericardial and bilateral pleural effusion, (3) ascites, (4) chronic passive congestion of liver, (5) chronic passive congestion of spleen with splenomegaly, and (6) follicular cyst of right ovary

Summary and Conclusion

A case of primary fibrosarcoma of the heart with metastases to the adjacent lymph glands, right lung, and spleen is presented because of its rarity

Although primary tumor of the heart is rare, it must be considered in the differential diagnosis of hemorrhagic pericardial effusion The failure to find malignant cells on careful examination of the fluid does not rule out this uncommon condition

I am very grateful to Dr Herman L Frosch for his kind criticisms and aid with this case

CEREBRAL HEMORRHAGE (NONTRAUMATIC) IN ADOLESCENCE

B EFFRON, M D , A A ROSENBERG, M D , and H MULLER, M D , Poughkeepsie, New York

(From the Departments of Pediatrics and Pathology, Vassar Brothers Hospital)

CEREBRAL hemorrhage (nontraumatic) is usually looked upon as an expression of severe vascular changes in advanced age However, even the early years of life may be abruptly terminated by intracranial hemorrhage, and the literature reveals that such situations are not too uncommon [1-1] Bagley writes, "I wish to emphasize that spontaneous cerebral hemorrhage is a common accident and may occur at any age "[12]

We are reporting on two cases of nontraumatic cerebral hemorrhage in adolescence.

Case Reports

Case 1 —M P , a white girl, age thirteen, was admitted to Vassar Brothers Hospital on July 2, 1947 She had been perfectly well until this time At 2 45 P M , while in a bank with her mother, she suddenly developed severe frontal headache She was taken home, the headache increased in severity, and she became delirious She vomited at about 4 00 P M , became comatose, and collapsed There was no history of any recent or remote head trauma, falls or accidents, or any recent illnesses Removal of tonsils and adenoids had been done two weeks before with no postoperative hemorrhage or complications Two years previously she had a lobar pneumonia which was treated successfully at home with penicillin There were no severe childhood illnesses The mother states that labor and delivery had been normal, and the neonatal period had been uneventful She had one brother, age eighteen, alive and well

Patient was comatose, making aimless motions with the right upper extremity and attempting to scratch the right nostril The right pupil was dilated and did not react to light The left pupil was normal in size and reacted to light The neck was not stiff, and there was no Babinski or Brudzinski sign The abdominal reflexes were absent The pulse was not obtainable, and the skin was cold and clammy The heart sounds were of poor quality, and there was a bradycardia, rate 44, regular The blood pressure was 100/60 There was no odor to the breath She had been brought to the hospital by ambulance.

A spinal tap revealed a pressure of over 800 mm of water The spinal fluid was pink, and on examination revealed 1 white blood cell, many red blood cells, and one plus globulin The eye grounds revealed some haziness of the disk margins A blood sugar test was reported as 219 mg per cent, and the urine revealed a 3 per cent sugar, 2 plus acetone, faint trace of albumin, and a specific gravity of 1 036 The temperature was 101 F by 8 00 P M , and she sank deeper and deeper into coma and expired at 11 00 P M., approximately eight hours after the onset of her headache The culture of the spinal fluid was sterile

Autopsy —Because of the difficulty in getting permission for the autopsy, only the head was examined, since the chief pathology was presumably there.

General External Appearance The body was that of a well-developed and well-nourished girl, thirteen years of age, who seemed to be mature for her age There were no external signs of injury The hair on the head was thick and abundant. The scalp was firmly adherent to the skull. The skull was thick but not abnormal and showed no fracture or sign of injury The dura was firmly adherent to the skull, as is usual in the young On removing the dura, the brain was found to be swollen, tightly filling the cranial cavity The convolutions were flattened out, and the sulci were obliterated so that increased intracranial pressure was indicated There was very little cerebrospinal fluid, the subarachnoid spaces being obliterated by the increased size of the brain There was no sign of hemorrhage on the external surface of the brain, nor was there any sign of trauma, such as lacerations The brain surface was pale, showing no congestion and no inflammatory exudate The consistency of the brain was definitely softer than usual so that removal was difficult There appeared to be no difference in the size of the left and right cerebral hemispheres First, the left lateral ventricle was opened by a longitudinal incision from above. This was normal in size and contained no excess fluid or blood Further longitudinal sections were made of the left hemispheres Nothing unusual was revealed Then the right lateral ventricle was opened, and this also proved to be negative, but on extending the incision backward, a poorly circumscribed cavity was revealed in the occipital lobe This cavity was covered laterally by a thin layer of cortex, thus not communicating directly with the surface of the brain The cavity was several centimeters in diameter, contained about 10 cc of dark red blood, evidently not absolutely fresh and bright red The cavity was lined with a thin layer of shaggy gray material with numerous prominent red spots, resembling the open ends of small blood vessels The cerebellum was normal Also the third and fourth ventricles were normal.

Microscopic Many sections were made of the wall of the cavity in the brain None of them showed any neoplastic tissue There were numerous small hemorrhages in the brain around the cavity, and there was blood on the surface of the wall of the cavity The cavity had no lining but consisted of brain tissue Gross and microscopic appearances were all in favor of a spontaneous intracerebral hemorrhage No single vessel from which the hemorrhage took place could be found

The diagnosis was spontaneous intracerebral hemorrhage.

Case 2 —F B , a white boy, age fourteen, was admitted on October 8, 1947 He had been apparently well for some time prior to admission and had no complaints until the morning of October 8, 1947 He had eaten a normal breakfast and had gone to school, where he became nauseous and vomited He was sent to lie down and was to be taken home but decided to go on his own and went outside and collapsed in the street He was brought to the hospital in a convulsive seizure He had had lobar pneumonia the previous winter and was treated with good results About three months previously he was at a Boy Scout camp where he

became ill. A stiff neck was noted for a few hours, but it did not persist. He recovered in two days, and the diagnosis was an upper respiratory infection. There was no history of headache, diplopia, vomiting, or an unsteady gait.

On admission the patient was comatose. The pupils were fixed to light, and there was marked nuchal rigidity. There was a positive bilateral Kernig's and an equivocal Babinski on the left. The heart and lungs were normal. The remainder of the body was not abnormal.

A spinal tap revealed a grossly bloody fluid under increased pressure. The blood pressure was 106/54. Blood sugar on October 8, 1947, was 162 mg. per cent, urea nitrogen 8.2 mg. per cent. Skull x-rays were normal, no fracture indicated. Blood count on admission revealed 102 per cent hemoglobin, 4,680,000 red blood cells, color index of 1.08, 12,900 white blood cells with 90 per cent polymorphonuclears, 9 per cent lymphocytes, and 1 per cent monocytes. White count repeated two days later showed 24,250 white blood cells, with 93 per cent polymorphonuclears and 7 per cent lymphocytes. A repeat spinal tap on October 10, 1947, was still bloody. Due to the grossly bloody characteristics of the spinal fluid a cell count and chemistry were not done. The temperature ranged from 100 to 102 F. He began to clear mentally but was drowsy and had a severe headache and stiff neck. A spinal tap one week after admission, taken on October 15, 1947, revealed xanthochromic fluid, and a pressure of 130 mm. of water. The spinal fluids of October 8 and 10 were reported sterile. On October 19 he had another convulsion, and the course was downhill. He became comatose, and another spinal tap revealed gross blood. A hemorrhage was noted in the left fundus oculi. He expired on October 22, 1947, fourteen days after onset.

Autopsy

General External Appearance. The body was that of a white boy, fourteen years of age, thin, with some loss of weight. There were no external pathologic signs.

Head. The scalp and skull were normal. There was no sign of fracture in the skull. The cranial cavity was first opened. The dura had a bluish tinge. On cutting it along the edges and lifting it off the brain, to which it was closely applied, very little spinal fluid was found to be present. In fact the surface of the brain was unusually dry. The veins were large, dilated, and very prominent. No free blood was present on the convex surface of the brain. The convolutions were flattened out, showing definitely increased intracranial pressure. On removing the brain, a small amount of dark red, slightly clotted blood was found on the surface of the anterior portion of the left frontal lobe. A small hole was present in the cortex on the undersurface of the left frontal lobe. The left frontal lobe was soft and fluctuant, and looking into the defect, there was seen to be a hemorrhage into the left frontal lobe. No more dissection of the brain was done, but it was removed in its entirety and put into formalin for fixation. At the base of the brain there were some small patches of clotted blood adherent to the brain.

After several weeks' fixation in formalin the brain was cut in many transverse sections.

Beginning at the circle of Willis in the region of the optic chiasma, there was found a large, thrombosed hemorrhage extending forward in the general direction of the left anterior cerebral artery. This clot was subarachnoid and extended into the brain tissue to a depth of 3 cm. and forward to the anterior surface of the left frontal lobe. It had ruptured through the base of the left frontal lobe so that some blood clots were found on the under surface of this lobe.

There was also present a large clot of blood in the left lateral ventricle distending the ventricle and extending backwards into the third and fourth ventricles and appearing also to a slight extent in the right lateral ventricle. This hemorrhage was most marked on the left side and from its appearance seemed to be of a later date than the hemorrhage of the left cerebral artery.

The gross description of the cerebral hemorrhages suggests that there was an initial spontaneous hemorrhage from the left anterior cerebral artery. This hemorrhage was fairly well organized. There was a later hemorrhage into the ventricles. Both were presumably not due to an injury, since there was no sign of it.

Diagnosis was spontaneous subarachnoid and intracerebral hemorrhage from left anterior cerebral artery, spontaneous intraventricular cerebral hemorrhage from choroid plexus, and emphysema of lung.

Comment

The youth of the patients may provide an obstacle to the diagnosis, but the suddenness and severity of cerebral symptoms usually leave no doubt as to what has transpired. There may be rapid exodus, as in Case 1, or the symptoms may be prolonged, as in Case 2, and the clinical picture, at least in the latter instance, is such that the diagnosis of meningitis must be considered. This is usually ruled out by the spinal fluid findings.

The combination of coma and hyperglycemia with glycosuria raises the very important question of diabetic coma. It is not unusual to find hyperglycemia with its attendant urinary findings in cases of cerebral hemorrhage. The differential diagnosis rests largely on the past history of the patient and the subsequent course. It is noted that both of these cases gave a recent history of lobar pneumonia, but it is hard to conceive that this infection had any part to play in the subsequent cerebral episodes, especially in view of the fact that in neither case was the pneumonia severe nor were there any complications. In Case 1 there had been a recent tonsillectomy and adenoidectomy, and again it would be hard to conceive any possible link between this and the hemorrhage.

It is difficult to imagine, as an isolated event, traumatic rupture of vessels situated deeply in the cerebral or cerebellar substance, and the difficulty is increased when no history of violence can be obtained. It is true that aneurysms give rise to cerebral hemorrhage in apparently healthy persons, but the vessels involved are usually those at the base of the brain and most commonly in or near the circle of Willis.[7] Capillary telangiectases are liable to give rise to intracranial hemorrhage in young adults but are most common in the posterior fossa.[8] Westphal is of the belief that cerebral hemorrhage is preceded by ischemia, the result of angiospasm.[14] During the angiospastic period the tissues surrounding the vessels are altered and when the spasm is relieved these tissues do not offer sufficient resistance to the vessel walls, and leakage results. Others feel that the failure of normal development of intra-

cranial structures offers greater response to less trauma, the type of trauma which ordinarily would have no effect.[5] Hypoplastic vessels as found in patients with the so-called "thymic syndrome" are more readily subject to rupture, even spontaneously, than normal vessels Forbus has shown that minute defects in the muscular coats of arteries, especially at vessel junctions, may be regarded as potential aneurysms or blow out points [15] Globus and Strauss have done a thorough study on the subject [16] They feel that there has been confusion between cause and result Their clinical and pathologic studies show that spontaneous cerebral hemorrhage is a terminal phase in a sequence of events. These events have their beginning in a generalized or somewhat localized disease of the cerebral vessels, which results in a closure of one or more of such vessels The area supplied by these vessels becomes ischemic, and there is consequent focal encephalomalacia With the production of such an area of softening, an area of diminished resistance is created, which is the important factor in the causation of the cerebral hemorrhage. Their cases included no young adults and parallel somewhat the theory advanced by Westphal.[14]

There is no unanimity of opinion as to the exact cause or causes for spontaneous cerebral hemorrhage in adolescence The two cases here reported do not offer any definite explanation as to causation but emphasize the fact that cerebral hemorrhage must be looked for and thought of even in young adults

Summary

Two cases of spontaneous cerebral hemorrhage in adolescents are presented with autopsy findings A short review of the literature and the prevailing views as to cause are included

PHYSICIANS FORM COMMITTEE TO STUDY TREATMENT OF ALCOHOLICS

A warning that untrue statements are being published about a newly discovered drug purporting "to cure alcoholism for a year with one dose" was issued today by Dr Edwin G Zabriskie, professor emeritus of clinical neurology at Columbia University College of Physicians and Surgeons, and consultant neurologist to the Neurological Institute of Columbia Presbyterian Medical Center Dr Zabriskie spoke as chairman of the newly formed Organization Committee for Research on Medical Treatment of Alcoholic Patients, which is developing plans for the investigation of a drug known as tetraethyl thiuram disulfide, now being used in Denmark and Sweden for the treatment of alcoholics.

"The Committee feels that the toxic properties and therapeutic value of this drug have not been fully explored," Dr Zabriskie states "Improper use of the drug may prove detrimental to the development of a sound treatment which would benefit hundreds of thousands of alcoholics According to the clinical reports of Danish physicians, the results of treatment with this drug are sufficiently encouraging to justify additional research, which should be completed before the drug is released by the United States Food and Drug Administration for general use by physicians in the treatment of alcoholics"

Other members of the Committee are Dr Oskar Diethelm, psychiatrist in chief, New York Hospital, Dr Ralph E Herendeen, roentgenologist, Memorial Hospital, Dr Walter W Palmer, Bard professor emeritus of medicine, Columbia University College of Physicians and Surgeons, Dr Thomas A C Rennie, associate professor of psychiatry, New York Hospital, Dr L Ogden Woodruff, president of the Health Council of Greater New York City, Dr A T Milhorat, associate professor of medicine, Cornell University Medical College, Basil G Eaves, former member of the staff of the National Tuberculosis Association and acting executive secretary

TRICHINOSIS COMPLICATING PREGNANCY

JEROME SCHWARTZ, M D , Bronx, New York

(From the Department of Obstetrics, Fordham Hospital)

BECAUSE of the difficulty of diagnosing the sporadic case of trichinosis and because of the rarity of this complication in pregnancy, the following case is presented

Case Report

L. A., a twenty-two-year-old, white, Italian war bride, para 0, gravida 1, was first seen in this hospital on November 6, 1947, when she was hospitalized for three days because of a mild chronic endocervicitis and cervical erosion At this time she was five months pregnant Expected date of confinement was March 11, 1948 On January 13, 1948, she was hospitalized for four days because of a right-sided pyelitis which responded readily to combined sulfa therapy

On February 5, 1948, she came to the clinic complaining of itching and swelling of both eyes At this time, the clinic physician thought she had a mild angioneurotic edema, and pyribenzamine, 50 mg a day, was prescribed. On February 10, the patient was seen in the admitting room of this hospital, where a diagnosis of mumps was made, and the advisability of transferring the patient to a contagious disease hospital was being considered As it was thought unwise to transfer the patient in her present condition, she was admitted to the isolation portion of the obstetrical service

Physical examination on admission revealed a well-developed, well-nourished white woman with such marked edema of the lids that the eyelids were practically closed There was also edema of the lower half of the face, especially pronounced in the *pre-auricular areas* There was a 1 plus pretibial edema and a 1 plus edema of the proximal portions of the carpal phalanges The muscles of the forearm, thigh, *and calf of the leg were tender to compression.* Homan's sign was negative bilaterally The remainder of the physical examination was essentially negative

The white blood count at this time was 22,300 with 77 per cent polymorphonuclears, 8 per cent lymphocytes, and 11 per cent eosinophils A diagnosis of acute trichinosis was entertained at this time, and with further questioning the following history was obtained from the patient

She was an Italian war bride who had been in this country for the past nine months On February 2, 1948, she and her husband had pork chops which were well cooked, since she knew that pork contained "worms" On Thursday, February 5, the day she appeared in clinic, she had noticed for the first time a peculiar swelling about her eyes The pills the doctor gave her did not help, for even though she took them as prescribed, the swelling about the eyes increased. On February 6, she began to have swelling of the face and hands That night her temperature rose to 102 F and was accompanied by bouts of shaking chills On February 8, patient noticed pains in the muscles of the forearm and calfs of her legs A private physician saw her on February 9 and recommended that she go to the hospital because she might have mumps She then appeared in the accident ward of this hospital for admission on February 10, eight days after the ingestion of the pork chops About 11 00 A M the patient was having irregular abdominal cramps, and it was believed that she was in early active labor

Although it was suspected that the patient had trichinosis, a number of tests were performed to rule out the possibility of the presence of any other disease causing this bizarre clinical picture Laboratory reports on the day of admission were as follows urine culture, negative, blood culture, negative, blood chemistry, sugar 125 mg per cent, urea nitrogen 26 mg per cent, agglutinations negative for paratyphoid A and B, Proteus X-19, Brucella abortus, and Typhoid H, Typhoid O positive 1 40, Kahn negative Urinanalysis revealed a specific gravity of 1 022, 1 plus albumin, and rare red and white blood cells per high power field

The medical consultant who saw the patient within a few hours of admission felt that the patient might have an erysipeloid infection of the face

That evening at 6 00 P M , the temperature rose to 105 6 F , pulse rate was 138, and the fetal heart rate was about 180 By rectal examination, the cervix was still thick and one finger dilated

At this point, although no cause could be found for the temperature, it was considered advisable to start the patient on 100,000 units of penicillin immediately followed by 50,000 units every three hours Alcohol sponges and tap water enemata were instituted to lower the temperature.

As the temperature persisted at about 105 F , combination sulfadiazine and sulfathiazole therapy with sodium bicarbonate was instituted at about 1 00 A M.

At 2 00 A.M of the morning of February 11, the fetal heart tones disappeared At this time the temperature was 104 6 F The cervix on rectal examination was two and a half fingers dilated, with pains occurring regularly every two minutes At 3 00 A M the patient was fully dilated and delivered spontaneously a stillborn male child weighing 7 lbs 8 oz , after a first stage of fourteen hours and a second stage of fifteen minutes

By 8 00 A M of February 11, the temperature was down to 101.2 F , pulse rate was now 152 and regular, blood pressure 98/74. Fundoscopic examination at this time with mydriatics revealed mild blurring of the nasal margins of the disks with a small round hemorrhage just above the macula at a bifurcation of the superior temporal retinal arteriole This hemorrhage disappeared within three days of the time it was noted. The retinal arterioles and veins were normal in appearance.

It was also noted on February 11 that the facial edema was subsiding somewhat, although muscular tenderness was still present White blood cell count on this date was 23,500 with 77 per cent polymorphonuclears, 14 per cent eosinophils, and 6 per cent lymphocytes A medical consultant on this day felt that the patient either had periarteritis nodosum or trichinosis

On February 12, the combination sulfa therapy was stopped, and immediate dehydration therapy with limitation of fluid and 50 cc of 50 per cent glucose three times a day was started, since it was

Presented at a meeting of the Bronx Obstetrical and Gynecological Society May 24 1948.

FIG 1 Low power magnification of unencysted, coiled Trichina larvae

felt that the patient was a severe pre-eclamptic in impending danger of having convulsions Streptomycin, 2 Gm daily in eight divided doses, was instituted on this day Although trichinosis was probably the most likely diagnosis, nothing was left undone in the way of therapy for the patient White blood count on this day was 28,000 with 40 per cent eosinophils, 57 per cent polymorphonuclears, and 2 per cent lymphocytes

Following the first injection of streptomycin, the temperature dropped precipitously within two hours from 104 F to 97 F, but within a period of eight hours had gone up again to 104 F Despite penicillin and streptomycin, the temperature continued to spike up to 104 F with almost daily remission to subnormal levels Penicillin and streptomycin were cut on February 14

Giemsa stain of the sediment of 5 cc of laked blood taken on February 15 revealed the presence of what was presumed to be trichina larvae On February 16 the precipitin test was performed by the New York Health Department and found to be strongly positive for trichinosis (immediate 1 320, two hours 1 1280) Skin test on February 18 was weakly positive for trichinosis. On February 25, twenty-three days after the initial infection, a biopsy of the gastrocnemius muscle revealed the presence of numerous motile trichinae slowly curling and uncurling themselves in a spiral fashion Histologic examination of the muscle revealed a focal and diffuse myositis with circumscribed accumulations of polymorphonuclears, lymphocytes, plasma cells, a few large monocytic macrophages, and only an occasional eosinophil In several areas unencysted coiled and straight trichina larvae were noted, surrounded by proliferating sarcolemmal cells and chronic inflammatory cells consisting, for the most part, of plasma cells, lymphocytes, and occasional polymorphonuclears and eosinophils (Fig 1) Digestion of 1 Gm. of same specimen of muscle also revealed the presence of 11 to 15 coiled larvae and about 20 small larvae, a very moderate infestation according to the classification of Hall and Collins.[1] It is interesting to note at this point that the gastrocnemius muscle at the time of biopsy appeared pale pink in color, edematous, and of almost a cystic consistency

From February 14 on, the fever exhibited almost daily remissions, but with each successive rise in temperature the peak would be slightly less than that of the previous day The peak of 46 per cent eosinophilia was reached on February 17, fifteen days after the initial infection After this date both the total white count and eosinophil count continued to decrease (Table 1)

Soft tissue x-rays of the muscles of the extremities and diaphragm taken on February 25 revealed no evidence of calcification

On March 4, thirty-one days after the pork had been ingested, the patient was discharged from the hospital afebrile but still complaining of slight pain and tenderness in the calf and thigh muscles

X-ray follow-up in May 1948 revealed no roentgenologic evidence of calcification of the cysts X-rays of diaphragm and lower extremities on May 14, 1949, fourteen months after onset of disease again revealed no roentgenologic evidence of calcification of the cysts.

Additional laboratory data were as follows February 20—cholesterol 180 Mg per cent, cholesterol esters 125 Mg per cent Urinary findings from date of admission to February 17, the urine contained 1 plus albumin and occasional white and red blood cells on microscopic examination After February 17, the urine was essentially negative. Electrocardiograms taken on February 13, 19, 27, and March 3 revealed no significant changes from normal (Table 2)

Autopsy of the stillborn child revealed no significant pathology, fetal death being attributed to the hyperpyrexia of the mother

TABLE 1.—CHANGE IN BLOOD COUNT DURING COURSE OF DISEASE

Date	Day of Disease	Red Blood Cells	Hemoglobin (Per Cent)	White Blood Cells	Eosinophils	Polymorphonuclears	Stab Forms	Lymphocytes	Monocytes	Basophils
Feb 10	8	2 000 000		22 300	11	77	3	8	1	
Feb 11	9			23 500	14	77	3	6		
Feb 14	13			22 500	34	53	5	7		
Feb 15	14	3 240 000	10							
Feb 17	16			30 250	46	46		8		
Feb 21	19			12 400	28	44		28		
Feb 28	26	3 640 000	66	12 200	24	55	2	16	3	1
Mar 2	29			11 150	14	40		46		

TABLE 2.—ADDITIONAL BLOOD CHEMISTRY FINDINGS

Date	Day of Disease	Sugar	Urea Nitrogen	Creatinine	Plasma Protein	Albumin	Globulin
Feb 11	9	125	26				
Feb 12	10		25 5				
Feb 16	14	83	20		5 1	2 7	2 4
Feb 17	15	90	14				
Feb 20	18	75	14	1 1			
Feb 24	22				7 6	2 9	4 7
Mar 3	30	82	12	1 5			

Digestion tests of the placenta, heart, liver, and diaphragm of the fetus revealed no trichina present

ACUTE MYELOGENOUS LEUKEMIA AND PREGNANCY

D J GRANDIN, M D , and H T POWERS, M D , New York City

(From the Department of Obstetrics and Gynecology, Lenox Hill Hospital)

THE coexistence of leukemia and pregnancy is rare. In 1943 McGoldrick and Lapp reviewed the literature and totaled 80 authenticated cases [1] Subsequent reviews and case reports brought the total to 92 [2–5] The present report brings the number of established cases to 93, 38 acute and 55 chronic

Case Report

The patient was a nineteen-year-old white primigravida, first seen in the Lenox Hill Hospital antepartum clinic on April 16, 1947 Her expected date of confinement was November 21, 1947

Her past history, family history, and menstrual history were normal

Physical examination revealed a somewhat undernourished woman. The remainder of the examination was normal The uterus was the size of a nine weeks gestation, and the pelvis was an adequate gynecoid Laboratory studies showed the urine and Wassermann negative, blood type A, Rh$_0$ positive, and hemoglobin 10 Gm

The patient was placed on iron therapy and followed at monthly intervals A marked generalized pallor was noted on October 16, 1947 A repeat hemoglobin was 7 5 Gm A subsequent blood count showed erythrocytes 2,000,000, hemoglobin 7.2 Gm., leukocytes 13,000 with 95 per cent "large lymphocytes," undoubtedly a misinterpretation

She was admitted for further study on October 27 It was elicited that she had noted recurrent, transient pinpoint red lesions on the skin throughout the pregnancy and increasing fatigue, back pain, and gingival bleeding during the month prior to admission

Physical examination revealed a pale but not acutely ill woman No rash, petechiae, or purpura were present No other abnormalities were noted The uterus was the size of a thirty-six weeks gestation.

Blood studies showed the erythrocytes to be 2,600,000, hemoglobin 8 1 Gm , white blood count 15,000, differential count, myeloblasts 78 per cent, myelocytes 1 per cent, polymorphonuclear neutrophils 4 per cent, lymphocytes 11 per cent, and monocytes 6 per cent, platelets 190,000 The sedimentation rate was 33 mm and 71 mm in fifteen and forty-five minutes, respectively, the hematocrit 25 per cent, mean corpuscular volume 96 cu. microns, mean corpuscular hemoglobin 30 micromicrograms, and mean corpuscular hemoglobin concentration 32 per cent The red cell fragility was normal Sternal bone marrow examination revealed almost complete replacement by myeloblasts The urine showed a trace of albumin 40 to 50 red blood cells, and occasional white blood cells A Rumpel-Leede test was strongly positive A cephalin flocculation test was 4 plus Additional laboratory studies were essentially normal (Table 1)

TABLE 1 —ADDITIONAL LABORATORY STUDIES

Chest film	Normal
Electrocardiogram	Normal
Basal metabolic rate	Plus 1
Heterophil agglutinins	Negative
Urea nitrogen	16 7 mg. per cent
Creatinine	0 5 mg per cent
Uric acid	4 5 mg per cent
Sugar	73 0 mg per cent
Carbon dioxide combining power	54 volumes per cent
Total serum protein	6 9 Gm
Albumin	3 9 Gm
Globulin	3 0 Gm
Icteric index	4 0
Prothrombin time	13 seconds (control 13 seconds)
Total cholesterol	181 mg per cent
Free cholesterol	73 mg per cent
Cholesterol ester	108 mg per cent
Alkaline phosphatase	4 3 Bodansky units

Therapy consisted of a high caloric, high protein diet multivitamin supplements with additional vitamin C, vitamin K and rutin, and transfusions

The temperature remained normal. Shortly after admission, nasal and gingival bleeding occurred, and petechiae appeared on the legs On the above regimen the bleeding phenomena decreased. By November 10 the erythrocytes were 3,700,000 and the hemoglobin 12 4 Gm

The next day labor ensued, and prophylactic penicillin was started. A healthy infant was delivered spontaneously, utilizing a small episiotomy The placenta and membranes were expressed intact followed by intravenous ergotrate The uterus contracted well The blood loss was estimated at 400 cc A 1,000 cc -transfusion was given after delivery The lochia was excessive only the first twelve hours postpartum Penicillin, vitamins, rutin, and transfusions were continued On the second postpartum day the erythrocytes were 4,400,000 and the hemoglobin 14 Gm

By the tenth postpartum day the general condition of the patient was fair, the uterus well in-

voluted, the episiotomy healed, the hemoglobin 10 Gm., the white blood count 18,600 with myeloblasts and myelocytes predominating, and she was discharged.

The patient was readmitted December 20 (thirty-nine days postpartum), having had pustular lesions of the skin, increasing anorexia, weakness, and five days of nasal and gingival bleeding, hematuria, fever, and headache. Vaginal bleeding had ceased one week before admission.

Physical examination revealed marked pallor and lethargy, temperature 102.4 F., pulse rate 110, respirations 20, and blood pressure 110/50. There were petechiae on the thighs, the liver, spleen, and uterus were slightly enlarged. The red blood count was 1,400,000, hemoglobin 4.0 Gm., the white count 22,500, with myeloblasts 86 per cent and myelocytes 1 per cent. Bleeding and clotting time were normal. The urine contained many red cells.

General supportive measures, including transfusions, were started. The subsequent course was febrile. Severe uterine bleeding started the second day and contributed heavily to the anemia that recurred in spite of transfusions. Curettage of the uterus and packing with oxidized gauze failed to control the bleeding. Packing with oxodized gauze and plain gauze with removal of the latter after fifty hours controlled the bleeding moderately well, but the patient continued a downhill course with signs of marked peritoneal irritation and expired sixty-one days postpartum.

Autopsy of the abdomen only revealed a myelogenous leukemic infiltration of the liver, spleen, adrenals, kidneys, mesenteric nodes, and uterus. The pancreas and ovaries were not involved. The uterus contained no endometrium, and the myometrium was necrosed. The lower aspect of the anterior wall contained a perforation leading retroperitoneally into the vesicouterine space. The bladder was intact. There was some hemorrhage into the broad ligament.

Discussion

The blood and bone marrow picture, absence of enlarged liver and spleen, and clinical course make this a case of acute leukemia. The onset was probably during the first trimester.

If a complete blood study had been done shortly after the first hemoglobin report, detection of the blood dyscrasia might have been earlier. In concord with Harris *et al* this suggests the importance of careful study of the blood picture in pregnancy.[2]

The relatively long course of this case may be attributable to penicillin, transfusions, and possibly rutin therapy. The management in general was conservative and supportive.

Curettage and tamponades of the uterus to control bleeding in the late postpartum period resulted in peritonitis and perforation of the uterus, the latter due either to instrumental perforation or rupture of the uterine wall due to erosion of the involved myometrium. Supravaginal hysterectomy might have been preferable or perhaps no uterine manipulations whatsoever.

Blood smears taken at delivery revealed no abnormal cells in the fetal blood. Sections of the placenta showed myeloblasts in the maternal sinuses only.

The baby's neonatal course was uneventful. Blood studies at four days and four weeks were normal.

Summary and Conclusions

1. A case of coexisting leukemia and pregnancy is reported.
2. The pregnancy, labor, and delivery were conducted conservatively and successfully. Penicillin, transfusions, and rutin were important therapeutic agents.
3. The necessity of careful evaluation of the blood picture during pregnancy is again re-emphasized.
4. The use of curettage and tamponade to control uterine bleeding in this type of blood dyscrasia is probably undesirable.

BUFFALO'S BANDWAGON

A sidelight on the way socialized medicine is working out in England from the point of view of the patient is given in a letter that indirectly has come to the Bandwagon. It was written by one who is not professionally interested in the question of socialized medicine. It was written with no thought that it would be seen by others than those to whom it was addressed. Because it does represent such a detached viewpoint, this excerpt is set forth here:

"The National Health Service, I feel sure, will break down and possibly bring the government down with it. Free doctors, free dentistry, free opticians, free hearing aids, free medicine. Oh, it is a lovely romp. Everyone who has a belly ache, tooth ache or minor ailment that should be forgotten runs to the doctor.

"I had necessity to go to the doctor last week and being a private patient of his for about 30 years phoned for an appointment. I kept the arrangement and was given preferential treatment. The waiting room was packed and a big argument arose because I was given preference over the national service freebooters as I call them. The doctor said he was booked until 10 P.M. and by the look of him he will break down under the strain. And there are four partners, all up to their necks.

"A little story of a doctor is worth telling. He came out of his consulting room, according to the story, and said to the crowds of patients, 'Now if any of you are suffering from nerves, go home for I am full of nerves myself', and many went home.

"It will be months before dentists and opticians can give attention and people wait months for hospital beds. This sort of thing never happened before the service came into force."—*Buffalo Courier-Express, April 11, 1949*

Special Article

THE AMERICAN ACADEMY OF GENERAL PRACTICE*

HOWARD A RUSK, M D , Associate Editor, New York *Times*, New York City

EARLY in March, a meeting that had real medical significance was held in Cincinnati. It was the first meeting of the American Academy of General Practice, an organization of more than 10,000 general practitioners

An attendance of 1,500 had been expected, but 3 500 family doctors came from all parts of the country, and they came with one primary purpose—to learn Every scientific section was crowded to the doors, with hundreds standing The attention was rapt, with at least half of the audience taking notes

Proud of their "specialty," the doctors attending had as their objectives improving the general practice of medicine and putting the family doctor back in his rightful place in the eyes of the public as the first line of medical defense

To be eligible for membership in the Academy of General Practice, a physician must have been graduated from an approved school, have a minimum of one year's approved rotating internship (they recommend two or preferably three years), be licensed to practice medicine in his state, and have shown a continuing interest in his medical advancement He must have been engaged in general practice for at least three years, and, to be eligible for continued membership, must spend a minimum of 150 hours in postgraduate training during his first three years in the Academy If these requirements are not fulfilled, he is dropped.

The Academy of General Practice resulted from a movement among groups of general practitioners from several states, who were convinced that progress and advancement in the general practice of medicine and surgery was basic to the welfare of the people and to the medical profession. They are not a political pressure group They declare that their aim is to work in close cooperation with the American Medical Association and other medical groups The potential membership is great, for there are estimated to be more than 100,000 general practitioners in the United States

In the undercurrent and overtones of the entire meeting, one sensed a tremendous, almost feverish desire to absorb every scrap of information. There were papers on surgical methods for the relief of intractable pain, cancer, the significance of "that old tired feeling", heart disease, obstetrics, malnutrition, industrial and rural medicine, and the problems of chronic disease.

The Congress of Delegates, policy-making body of the Academy, worked on resolutions reflecting the Academy's stand on a number of controversial medical problems After asserting their unqualified opposition to compulsory health insurance, the Congress of Delegates passed the following resolution

"We recognize the great advances made in health insurance in the past ten years by private insurance carriers as well as by Blue Cross and Blue Shield and others on a voluntary basis We wish these agencies and companies to know that the American Academy of General Practice offers them full support We encourage them to continue to offer to the people of America a variety of types of voluntary insurance, placing greatest emphasis on that type which covers 80 to 90 per cent of the medical and hospital costs"

Another critical problem considered in the Congress of Delegates was the matter of hospital training for physicians entering general practice After discussion, they recommended two years' hospital training as a desirable minimum, which would include a broad program in medicine, pediatrics, obstetrics, gynecology, and surgery, pointing out that they do not expect to turn out finished surgeons, but doctors able to make surgical diagnoses, take care of minor surgical procedures, and be responsible for major surgery until they can get adequate help

They also ask a place on the hospital staff for the general practitioner, and wisely do not ask that he be admitted on the unlimited status of the specialist, but that he should have professional privileges commensurate with his ability, specifying this as follows

(*a*) Minor privileges in any service will allow the physician to treat patients when, for any cause the treatment does not involve either a serious hazard to the life of the patient or a danger of disability

(*b*) Intermediate privileges in any service will allow the physician to treat patients when, for any cause, such treatment does not involve a serious hazard to the life of the patient, but does involve a danger of disability

(*c*) Major privileges in any service will allow the physician to treat patients when, for any cause, such treatment involves a serious hazard to the life of the patient In the performance of clinical procedures or in the management of patients in the hospital, the ultimate evaluation of the judgment and ability of the general practitioner shall rest with the Qualifications and Credentials Committee

Such a program would give the general practitioner an opportunity to look after his own patients in the hospital and would safeguard the patient against some of the more radical members whose judgment of ability might be questioned by other professional members on the hospital staff

It was heartening to attend the initial meeting of the American Academy of General Practice, heartening, because of the high caliber of the men present It made one feel good to know that the primary responsibility of medical care in this country is in their hands The tempered judgment of their deliberations, that recognized both the abilities and the limitations of the physicians doing general practice, made evident the breadth of concept of this group The eagerness with which they sought medical truth presages a bright future for medical progress

* Abstract of an article which appeared in the New York Times March 13 1949

SUMMARY OF MINUTES OF THE COUNCIL OF THE MEDICAL SOCIETY OF THE STATE OF NEW YORK

AT ITS meeting on April 14, 1949, the Council considered the following matters, taking action as indicated

Secretary's Report

Remission of Assessments—Remission of annual assessments was voted on account of service with the armed forces for two members for 1949, 14 for 1948, one for 1947, and, on account of illness, five for 1949, and 9 for 1948 Nine War Memorial assessments were remitted on account of illness and five on account of service with armed forces

After discussion, *it was voted* to disapprove a recommendation to remit Dr William J Garvin's 1949 dues because of his serving a postgraduate residency

It was voted to reconsider the actions of March 10, 1949, to remit 1949 dues for Dr Oliver T Ghent and Dr Joseph C Tedesco because they were serving postgraduate residencies

Dr Anderton stated that Wyoming County had been notified that the Council had remitted the dues for Dr Oliver T Ghent and Dr Joseph C Tedesco

After discussion, *it was voted* that this request from Wyoming County Medical Society be denied, and the Secretary instructed to write that the previous action had been contrary to the bylaws

It was voted that this matter be referred back to the secretary of Wyoming County Medical Society suggesting a resolution on this subject be introduced in the House of Delegates of the State Society

A request from the Medical Society of the County of Kings for the remission of 1948 dues and War Memorial assessment for Dr Charles L Stone who is to be nominated to be a retired member was denied, on account of insufficient information.

A request from the Medical Society of the County of Kings for refund of 1949 dues for Dr Joseph Dolin was considered Dues were paid in January In February Dr Dolin resigned and moved to New Jersey

After discussion, *the motion to refund was decided* by a rising vote, 11 for and 5 against

Dr Martin B Tinker, Sr, Tompkins County Medical Society, was nominated for Associate Fellowship in the American Medical Association

Communications—1(*a*) Letter from Dr Charles F McCarty, secretary, Coordinating Council of the Medical Societies of Bronx, Kings, New York, Queens, and Richmond, dated March 31, 1949, requesting the appointment of a representative from the Coordinating Council as a member of the Legislative Committee of the State Society (*b*) Resolution dated April 12, 1949, requesting an increase of the Committee on Legislation to seven members, four to be selected from Greater New York City, and urging the procurement of an assistant for the Executive Officer at Albany at the earliest possible moment

After discussion, *it was voted* to request Dr Masterson and Dr Holcomb to meet a representative or two from the Coordinating Council to obtain information and report

2 Letter dated March 24, 1949, from Dr John J Finigan, president, Medical Society of the County of Monroe, enclosing resolution endorsing the American Medical Association twelve-point plan for the advancement of medicine and public health, and opposing compulsory health taxation bills.

3 Letter dated March 17, 1949, from Dr Joseph A Geis, Lake Placid, requesting copy of Council minutes every month.

It was voted that the Secretary should write Dr Geis that if it is difficult or inconvenient for him to obtain the minutes from his county society secretary, he let the Society office know and we will supply him with a copy

4 Letter, March 15, 1949, from Dr Charles H Loughran, secretary, Medical Society of the County of Kings, requesting refund of 1949 assessment to the Estate of Dr Henry J Goubeaud, Jr Dr Goubeaud died on February 10, 1949 His assessment had been paid on January 13

After discussion, *it was voted* that the Secretary inquire if there are any extenuating circumstances.

5 Letter from Dr Darrell G Voorhees, chairman of the Section on Ophthalmology and Otolaryngology, with a request from Dr James S Greene, a speaker on the annual meeting program, who would like the Society to pay expenses of one patient from New York to Buffalo and back for demonstration. The cost would be approximately $50

It was voted that the Secretary write Dr Voorhees that the Council considers it would be a bad precedent to pay such expenses

6 Letter dated March 30, 1949, from Mrs Mabel Detmold, president of the New York State Nurses Association, to Dr Frey, chairman of the Committee on Nursing Education, in regard to improving cooperation between hospitals, doctors, and nurses

7 Letter dated March 29, 1949, from Mr Louis Schenkweiler, president of the Greater New York Hospital Association, to Dr Simpson, State Society President, urging the necessity for better coordination of legislative programs of the medical societies and the Greater New York Hospital Association

After discussion, these two letters were referred to the new special committee regarding legislative matters, consisting of Dr Masterson and Dr Holcomb

8 Letter dated April 8, 1949, from the Committee of Revision of the U S Pharmacopoeia 1940–1950, requesting a contribution to its building fund

After discussion, this request was referred to the Board of Trustees with the notation that the Council looks favorably upon it

9 Letter dated April 13, 1949, from the American Museum of Health, Inc, requesting endorsement for establishment of a Museum of Health in the City of New York

After discussion, *it was voted* to refer the matter to the Public Health and Education Committee

At the last meeting of the Council you voted to request that the Board of Trustees appropriate $150 toward expenses of the Middle Atlantic States Conference on Medical Service, of the American Medical Association This recommendation is being studied by the Board of Trustees and will be considered on April 14 In accordance with your recommendation, $20,555 was appropriated by the Board of Trustees on March 14, 1949, for *Directory* deficit An appropriation of $75 for one delegate to the U S Pharmacopoeial Convention was also voted by the Board of Trustees as recommended by you

On March 15, 1949, your Secretary conferred with Professor Eli Ginsberg of the Department of Economics of Columbia University and his associate, Dr Saunders These gentlemen are studying the economic situation of hospitals for the State legislature

At the February 10, 1949, meeting of this Council recommendation was voted to the Board of Trustees that $50 be appropriated for expenses of the Conference of Presidents and Other Officers of State Medical Associations At its meeting on March 10 the Trustees referred this recommendation back to the Council for further consideration

It was voted that this again be submitted to the Trustees, with the understanding that the Secretary read an explanatory letter received from the Conference

Your Secretary has attended all committee and board meetings since last month

The Treasurer's report was accepted

Reports of Committees

Legislation.—After discussion,

It was voted that the Speaker invite Miss Mary Donlon to address the House of Delegates regarding Assembly Introductory Bill 3063 (Mr Mailler)

Dr Holcomb, chairman, added that improved coordination was needed to obtain favorable action on our legislation

Economics—Mr Farrell, director of the Medical Care Insurance Bureau, reported he had spoken on medical care plans before several meetings

He presented the fourth Quarterly Progress Report on the voluntary medical care insurance plans Also, the Third Annual Progress Report has been mailed to presidents and executive directors of New York State Plans, members of the Subcommittee on Medical Expense Insurance, Council and Board of Trustees as well as to others interested in voluntary medical care insurance Additional copies are available

The Bureau is developing a pamphlet for distribution at the Annual Meeting, containing progress of the plans and an abstract report to members of the Society on the activities of the Subcommittee on Medical Expense Insurance during the past year These pamphlets will also be distributed by the Public Relations Bureau with its News Letter

Dr Wertz, chairman, read a resolution on Maimonides Hospital passed by the Medical Society of the County of Kings February 15, 1949, urging the Board of Directors of the Maimonides Hospital to reconsider their limiting staff membership to one field of medicine and to retain general practitioners on the staff This the Board had refused, and Kings County requests the Medical Society of the State of New York and the American Medical Association to urge the Board of Directors of Maimonides Hospital to reconsider

After discussion, *it was voted* that the Secretary refer this matter to the Council on Education and Hospitals of the American Medical Association for information

Ethics.—Dr Reuling, chairman, read a letter from the Secretary of the Medical Society of the County of Cayuga and from Dr Walter C Levy, District State Health Officer, in reference to members of the Cayuga County Medical Society participating in a radio program that has not been passed upon by the County or State Society

Dr Reuling stated there had been no meeting of the Committee on Ethics, but in the opinion of the chairman this should be purely a county society matter As long as there is nothing in the platter prepared for broadcast that is contrary to our Code of Ethics, he could see no reason why the county society should not cooperate and have any members follow the formal program with individual comment Dr Reuling stated he had talked with Dr Curphey, chairman of the Public Health and Education Committee, and that Dr Curphey was in agreement with that opinion

It was voted to approve the report and recommendations

Malpractice Insurance and Defense Board.—The following actions were taken on matters presented by the Committee

It was voted to authorize the discontinuance of a certain doctor's policy or policies when they expire on July 7, 1949

It was voted that members in good standing in the New York State Homeopathic Medical Society be allowed to participate in our Group Malpractice Defense Insurance

At its meeting on April 6 the Malpractice Insurance and Defense Board decided that it would be desirable to have Mr Joseph Linder present to the House of Delegates in person his report of the audit and actuarial study of the Society's Group Malpractice Insurance for the year 1948

It was voted to approve Mr Linder's proposed attendance and to request the Board of Trustees to appropriate $55 to cover his expenses

Publication Committee—Dr Kosmak, chairman reported that the Committee met April 13 and a number of routine matters were discussed The JOURNAL and *Directory* are running within the budget, and the advertising income for the first three months of the year has been above that for the same period in 1948 This has permitted continuation of the additional 16 pages of scientific material

Public Health and Education.—The Council voted to express appreciation to Dr Charles D Post for his careful and efficient work as Acting Chairman of the Public Health and Education Committee

Dr Curphey, the new chairman, added his personal thanks to Dr Post and Mrs Virginia Kelley for the splendid help they had been to him in the process of being initiated in his new task.

He reported that Dr Larimore, director of the Office of Public Health Education of the State Health Department, requests the State Society to organize a committee to review movie films that are available for health education He pointed out that the Council on October 14, 1948, voted the establishment of a motion picture review board, appointments to which would be made by the President when, as, and if necessary

The President was empowered to appoint this Committee

It was voted to approve Dr Larimore's request for approval of free distribution in doctor's offices of pamphlets on diabetes, heart disease, and arthritis, prepared by the State Health Department

It was voted that approval be expressed of the program for demonstration of adult heart disease prepared by the State Health Department

The recommendation that the Board of Trustees be requested to appropriate $75 for Dr William E Ayling's expenses as representative of the Society at the Conference on Physicians and Schools at Highland Park, Illinois, October 13 to 15, 1949, *was approved*

Public Relations—Dr Winslow, chairman, reported activities and immediate objectives.

Veterans Administration, Liaison with.—Dr Wertz reported for Dr Bauckus that he had signed a renewal of the existing contract with Veterans Administration for three months and that Dr Bauckus intends to be in Washington next Wednesday to confer with Dr Magnuson, head of the Veterans Administration, and representatives of the American Medical Association

Workmen's Compensation.—Dr Kenney, chairman, reported on the activities of this Committee

New Business

It was voted to appoint a representative of the Society as a member of the Industrial Cancer Committee of the New York State Department of Labor

It was voted that the proposal of Dr John L. Bauer for membership on the Disciplinary Committee of the Board of Regents be endorsed.

It was voted to make the date of the June Council meeting *Thursday, June 16, on account of the* meeting of the American Medical Association.

Dr Simpson thanked the Council for their consideration and kindness during the past year

Dr Masterson stated "Unless we have some special meeting, this will be the last meeting for Dr Simpson to preside I would like, sir, to spread upon the minutes of our Council our thanks and appreciation for the patient, fair, dignified, and courteous manner in which you have conducted these meetings"

The motion was put to a rising vote and amid applause *was carried* unanimously

---

ADVISE CAUTION IN USE OF DICUMAROL

Dicumarol, a drug which prevents clotting of the blood, should be used with extreme caution, warn three Chicago doctors and two Ann Arbor, Michigan, doctors in the March 19 issue of the *Journal of the A M A* In no case should the drug be used unless reliable laboratory facilities for testing prothrombin, a factor involved in clotting, are present, say Ivan F Duff, M.D , and William H Shull, M D , from the Department of Internal Medicine, University of Michigan, and the University of Michigan Hospital The drug should be used with caution in patients with severe high blood pressure The Ann Arbor doctors report a case of death, apparently from dicumarol, at the University Hospital

They report seven deaths attributed to dicumarol among patients with subacute bacterial endocarditis—inflammation of the membrane which lines the heart—and 16 deaths attributed to dicumarol among patients with other conditions These 23 deaths occurred at various places other than the University of Michigan Hospital.

Animal experiments show that dicumarol treatment is not advisable for pregnant women advise Alfred P Kraus, M.D , Samuel Perlow M D , and Karl Singer, M.D , from the Department of Hematologic Research, Medical Research Institute, and the Department of Surgery Michael Reese Hospital, Chicago

---

DEATHS IN 1948

While deaths from all causes among ordinary life insurance policyholders occurred at a new low rate in 1948, heart deaths accounted for more than half of the total, the Institute of Life Insurance reports The heart disease death rate rose last year to a record high Total deaths per 100,000 were 625 1 in 1948, compared with 668 8 in 1946 and 751 2 in 1944 Deaths from the chief cardiovascular-renal diseases, commonly called heart disease, were 327 9 per 100,000 in 1948, 325 4 in 1946, and 324 1 in 1944 These include diseases of the heart, cerebral hemorrhage and nephritis, and together represented 52 per cent of total deaths in 1948

Cancer, second most important cause of death, accounted for 98 7 deaths per 100,000 last year, compared with 98 0 in 1946 and 92 7 in 1944. Accidents had a death rate of 42 7 in 1948, 48 4 in 1946, and 52 4 in 1944. This improvement was shown even though motor vehicle accidents rose from 13 in 1944 to 18 2 in 1948 Tuberculosis deaths declined to a record low rate of 11 4 per 100,000 in 1948, one-third less than in 1944

The 1948 experience among industrial insurance policyholders followed a similar pattern, but on higher level, due to the difference in the types of business *Industrial insurance policyholders are not* generally subject to medical examination when applying for policies

In 1948, the deaths from all causes among industrial insurance policyholders were 771 9 per 100,000, compared with 834 4 in 1946 and 867 in 1944 The deaths from diseases of the heart in 1948 were 357 8 per 100,000, or 46 per cent of the total deaths

RAY-TROTE
IMPROVED

a 'step-down transformer' for the management of hypertension

An *increased dose* of chemically standardized, *physiologically active* veratrum viride distinguishes the new RAY-TROTE IMPROVED CAPSULES by *Raymer* Three effective vasodilators—nitroglycerin, sodium nitrite, and veratrum viride—are combined in the capsule A mildly sedative dose of phenobarbital in the formula helps to maintain lowered blood pressure levels Based on a formula used by physicians for nearly a quarter of a century now made even more effective Prescribe it in your next case of hypertension

Formula: Phenobarbital ¼ grain; Sodium Nitrite ½ grain
Nitroglycerin 1/250 grain Potassium Nitrate 1 grain
with equivalent of Veratrum Viride Tincture (containing 0.1% alkaloids) 4 minims; Crataegus Fluidextract 1 minim

Sample and literature sent on request.

Available at all pharmacies on prescription.

NECROLOGY

Achille Frank Baratta, M D, of the Bronx, died on May 12 of a heart attack while driving his car across the Triborough Bridge from Manhattan to the Bronx He was fifty-two A native of Naples, Italy, he came to this country as a boy, and received his medical degree from Tulane University Medical School in 1921 Dr Baratta was assistant physician at the Morrisania Hospital Outpatient Department He was a member of the Bronx County and New York State Medical Societies and the American Medical Association

Philip L Bereano, M D, seventy, of New York City, died May 22 in St Luke's Hospital, after a brief illness Born in Rumania, Dr Bereano received medical degrees from the University of Bucharest in 1905 and the Long Island College Hospital Medical School in 1909 At one time he had been examining physician for approximately forty Rumanian-American organizations and had served on the staffs of the Lebanon, Morrisania, and German Polyclinic Hospitals Dr Bereano was a founder and member of the medical staff of the Jewish Home for Convalescents, Grandview-on-Hudson

Francis A. Birch, M D, of White Plains, died at his home on May 10 at the age of seventy-one A graduate in 1905 from the New York Homeopathic Medical School, Dr Birch interned at the Metropolitan Hospital, New York City, and opened his practice in White Plains in 1907

Edwin Crosby Chamberlin, M.D, seventy-nine, of Brewster, died on May 23 He received his medical degree in 1894 from the College of Physicians and Surgeons, Columbia University, and retired several years ago from his general practice of medicine

Gerhard Hecht, M D, of Union, died on May 2 Dr Hecht received his medical degree in 1925 from the Friedrich Wilhelm University of Berlin, Germany He was a member of the Broome County and New York State Medical Societies, and the American Medical Association

Roy Biggs Henline, M D, of New York City and Bronxville, died on May 23 at the New York Hospital after an illness of three weeks He was fifty-four Dr Henline was graduated from the Northwestern University Medical School in 1919 and served his internship at the Michael Reese Hospital in Chicago, after which he was a resident physician at New York Hospital He opened his practice in New York City in the early 1920's and was approved as a specialist in urology upon the foundation of the American Board of Urology in 1935

Dr Henline was attending surgeon and urologist for the James Buchanan Brady Foundation at New York Hospital and director of urology at Sydenham Hospital He was also consulting urologist for St Luke's Hospital, Newburgh, the Yonkers General Hospital, and the Mount Vernon Hospital In 1939 Dr Henline served as chairman of the Special Committee for Medical Information Service for World's Fair visitors He was chairman of the New York County Medical Society's committee on hospitals and dispensaries in 1938 and chairman of the committee on medical economics in 1939 In 1946 he became president of the New York County Medical Society, and in his inaugural address strongly opposed legislation for national compulsory health insurance

Dr Henline was active in planning medical aid for veterans after World War II He was a director of the Associated Hospital Service, a founder of the United Medical Service, and a Fellow of the New York Academy of Medicine and the American College of Surgeons He was a member of the American Urological Association, the New York County and State Medical Societies, and the American Medical Association

Alexander Leon Louria, M D, fifty-nine, of Brooklyn, died May 22 at the Jewish Hospital of Brooklyn after an illness of several months A native of Moscow, Dr Louria came to the United States when he was a year old He was graduated from the College of Physicians and Surgeons, Columbia University, in 1913, and in 1926 joined the staff of the Long Island College of Medicine as clinical professor of medicine Dr Louria was attending physician at the Jewish Hospital of Brooklyn, a director of the American Jewish Physicians Committee, a former director of the Brooklyn Federation of Jewish Charities, a Diplomate of the Society of Internal Medicine, and a member of the Williamsburg Medical Society, the Kings County and New York State Medical Societies, and the American Medical Association

Adelaide Mills, M.D, of St. Albans, died on January 21 at the age of eighty-eight Dr Mills received her medical degree in 1903 from the New York Eclectic Medical College

Edward Lord Mulford, M D, of Ithaca, died on May 13 A graduate of the Yale University School of Medicine in 1931, Dr Mulford was senior tuberculosis physician at the Hermann M Biggs Memorial Hospital in Ithaca. He was a member of the Tompkins County and New York State Medical Societies and the American Medical Association

Louis Michael Palermo, M.D, forty-seven, Bronxville, died on May 8 at Mount Sinai Hospital, New York City Dr Palermo was graduated from the New York Homeopathic Medical College in 1928 He was associate surgeon at the Metropoltan Hospital and assistant attending surgeon at the Flower and Fifth Avenue Hospitals, in New York City A Fellow of the American College of Surgeons, Dr Palermo was a member of the New York County and State Medical Societies and the American Medical Association

Nathan Israel Slutsky, M D, of Brooklyn, died on May 13 at the Brooklyn Jewish Hospital at the age of sixty-four Dr Slutsky was graduated from the Cornell University Medical College in 1907 and interned at Sydenham Hospital before opening his practice in Brooklyn He was attending surgeon in urology in the Beth Moses Division of Maimonides Hospital, Brooklyn, and a Fellow of the International College of Surgeons Chairman of the board of the Doctors Club of Brooklyn, Dr Slutsky was a member of the Kings County and New York State Medical Societies and the American Medical Association

MEDICAL NEWS

Army Needs Public Health Officers

THE Department of the Army is urgently in need of Public Health Officers to serve in a civilian capacity with the occupation forces in Japan These positions, which involve supervision of Japanese prefecture (state) health departments in all phases of preventive medicine and medical care programs, offer an excellent opportunity for broad experience in public health

Minimum acceptable qualification requirements are a degree in medicine plus one year internship Experience in public health is desirable but is not mandatory

The salary for these positions is $6,235.20 per annum plus 10 per cent post differential with quarters provided at no cost to the employe Individuals selected for appointment must agree to remain a minimum of two years Transportation is furnished to and from Japan Dependents may join the employe in approximately six to eight months

Interested applicants may make formal application by submitting Civil Service Commission Standard Form 57 to the office of the Secretary of the Army, Washington 25, D C Forms may be obtained from any Class A Post Office

Adult Heart Educational Program

THE New York University-Bellevue Medical Center will present two short courses in cardiovascular diseases for general practitioners as part of the Adult Heart Educational Program being conducted by the New York State Department of Health and the Medical Society of the State of New York. The New York City Department of Health is also acting as a sponsor for courses being given in New York City These courses are designed to assist the general practitioner in the management of his patients with diseases of the heart and peripheral vascular system by bringing him up to date regarding recent developments in diagnosis and treatment

The first course will be offered by the New York University College of Medicine at Bellevue Hospital and will run for three days beginning Monday, June 20, 1949 The other course will be offered at the New York University Post-Graduate Medical School, 356 Second Avenue, New York, and will run for four days beginning Monday, June 27

Physicians interested in either course should advise The Recorder, New York University Post-Graduate Medical School, 356 Second Avenue, New York, stating which course they desire and also whether they would accept the other if the first is already filled. A registration fee of $3 00 should accompany the letter Checks should be made payable to New York University The registration fee will be returned to applicants who cannot be accepted because of filled quotas

The New York State Department of Health will provide fellowships for all accepted students to cover the tuition fees in full. In addition, the Department will provide a stipend of $10 per day to cover travel or living expenses to those students living 25 miles or more from the school

Lectures at the New School for Social Research

FOUR Nobel prize winners and other leaders in the field of biochemistry and related sciences are scheduled to lecture at the New School for Social Research next fall, Dr Bryn J Hovde, president of the New School, has announced Their lectures are part of a greatly expanded program in science developed at the New School which includes a group of six courses on biochemistry offered as a public service and without fee and given jointly by the New School and the Institute for Muscle Research under the direction of Dr Albert Szent Gyorgyi, distinguished Hungarian scientist

Dr Szent Gyorgyi and the group from the Institute for Muscle Research which he heads have been arriving in this country since last fall from Hungary at the invitation of the New School The Institute is currently conducting research at Woods Hole, Massachusetts, centering in the study of muscle, physics of the living state, and study of blood

Besides Dr Szent Gyorgyi, who won the Nobel prize in medicine and physiology for the discovery of Vitamin C and fumaric acid catalysis, 1937, the other Nobel prize winners who will lecture at the New School are the outstanding scientist, Dr Otto Warburg, of the Institute for Muscle Research, who received the Nobel prize in medicine in 1931 for discovering the character and mode of action in the respiratory ferment, Dr Otto Loewi, now research professor of pharmacology, New York University College of Medicine, who won the Nobel prize in 1936 with Sir Henry H. Dale for discoveries in the field of chemical transmission of nerve impulses, and Dr Ottl Meyerhof, research professor in physiology, University of Pennsylvania, who shared the Nobel prize in 1923 with Dr Archibald V Hill and who established the correlation between the consumption of oxygen and production of lactic acid in muscle

The courses, which run from seven to sixteen weeks each, are of two kinds The first two, "Dynamics of Living Things," and "Dynamics of Muscle as a Living System," are addressed primarily to the intelligent layman, and it is in the first of these courses that the Nobel prize winners and other leaders in the field will appear The remaining courses are designed more expressly for members of the medical profession and other scientists These courses include "Biochemistry of Muscle," "Blood and Some Aspects of Its Functions," "Elementary Introduction to Quantum Mechanics and Some Biological Applications," and "Quantum Chemistry and Its Biological Applications"

Besides those already mentioned these speakers

include Drs Robert Chambers, research professor of biology, New York University, Leonor Michaelis, Rockefeller Institute for Medical Research, DeWitt Stetten, Michael Heidelberger, professor of immunochemistry, College of Physicians and Surgeons, Columbia University, Homer Smith, professor of physiology, New York University College of Medicine, and Ernst Mayr, curator, Whitney-Rothschild Collections, American Museum of Natural History

Three ranking scientists, Dr Andrew Paul, Dr Ephraim Shorr, and Dr Harold G Wolff, join Dr Kalman Laki, Dr Stephen Rath, and other members of the staff of the Institute for Muscle Research in giving the course, "Blood and Some Aspects of Its Functions" Dr Paul is president of the American Academy of Allergy, Dr Shorr is associate professor of medicine and Dr Wolff is professor of neurology and psychiatry at Cornell University Medical School Dr Laki is a biochemist, and Dr Rath a specialist in translating laboratory methods into mass production

Special topics to be discussed in the course especially designed for scientists under the heading of "Biochemistry of Muscle" include the structure of muscle and the structure of sarcolemma, utilization of energy in enzymatic and synthetic processes, conditions of thermodynamic equilibrium and the energy relations in muscle fibers, and a thermodynamic explanation of muscle contraction The course, "Blood and Some Aspects of Its Functions," will discuss the fundamental biochemistry of blood functions and certain related clinical manifestations of body disturbances Other topics are the mechanism of blood clotting, the general biological aspects of blood functions, the histamine theory of allergy, hemorrhagic and traumatic shock, experimental and human hypertension, and prognosis and dietary v surgical treatments "Quantum Chemistry and Its Biological Application" among other topics will discuss the application of wave mechanism to chemistry and the chemistry and structure of proteins

For further information address the New School at 66 West 12th Street, New York 11, New York.

MEDICALLY SPEAKING—

The New Israeli Medical School—The official opening of the Hebrew University-Hadassah Medical School was marked on May 17 by ceremonies both in Jerusalem and New York City, at which prominent representatives of government, public health agencies, and medical schools participated In Jerusalem temporary buildings will serve until the new structures to be erected on Mt Scopus are ready for occupancy The Medical School is the first institution of its kind in the new State of Israel, and it will also serve as a center for research in the diseases prevalent in the Near East—trachoma, malaria, tuberculosis, and enteritis The creation of a school of high rank is an indispensable basis for improved health work, according to Dr Herman E Hilleboe, New York State Commissioner of Health, in his greeting to the new medical school

Official Resolutions Against Compulsory Health Insurance—It has been announced through the office of the National Education Campaign of the American Medical Association that 616 organizations are on record as having passed formal resolutions in opposition to compulsory health insurance This list includes not only state and county medical societies from all parts of the country, but women's auxiliaries, clubs, businessmen's organizations, and many others The listing undoubtedly will be expanded when people get the facts about compulsory health insurance and how serious would be the results of its imposition More of this effort is essential

Study on the Industrial Physician—At a recent meeting of the Louisville, Kentucky, section of the American Academy of General Practice, Dr Leonard J Goldwater, professor of industrial hygiene at Columbia University, told the Academy that if a study just completed by Columbia University's School of Public Health is a criterion, the plant doctor plays a vital role in the prevention and early diagnosis of disease among production workers

The study reveals that in two comparable industrial plants in New York City, the plant which maintains an industrial physician had more than twice as many of its employes visiting family physicians during a year's time as did the plant which does not keep a doctor on its rolls

Conducted by a group of investigators headed by Dr Goldwater and Dr Meyer Rosenblum, also of Columbia, the study shows that the plant with a physician in attendance referred on to family doctors 17 per cent of the plant personnel, as contrasted with the nonmedical service factory in which only 7 3 per cent of its employes visited their doctors

Increase in Tuition Fees—In a recent statement by Dean Currier McEwen of the New York University College of Medicine, an increase in the tuition fees for the College was announced, as follows "Beginning with the academic year, 1949-1950, the New York University College of Medicine will increase its tuition fee from $650 to $750 Although the new rate is in line with the charges now being made by other leading medical schools, the University has delayed making this increase as long as possible It has become impossible for the University to carry the increasing annual operating deficit to as full an extent as it has in recent years, and there remained no choice but to follow the example of many other medical colleges and increase tuition"

Receives Alumni Honor—Among the six alumni who received the New York University Alumni Meritorious Service Award for 1949 for "distinguished service to the University," was Dr Ralph L. Dourmashkin, a graduate of the Medical College in 1915 The group were guests of honor at the annual medallion dinner on May 24

Longevity and Mortality of Physicians—The Metropolitan Life Insurance Company announces an offer, without charge and on a permanent basis if desired, of a limited number of exhibits entitled "Longevity and Mortality of Physicians" This material contains the results of a study showing what the men and women of the medical profession have accomplished in protecting their own health A limited number of descriptive brochures is also avail-

able and will be furnished upon request This material is available for annual or special meetings or on a permanent basis in connection with teaching programs For further information, apply to Dr Donald B Armstrong, 1 Madison Avenue, New York 10, New York

International and Fourth American Congress on Obstetrics and Gynecology—The Scientific and Educational Exhibit Committee of the International and Fourth American Congress on Obstetrics and Gynecology, under the chairmanship of Dr John Parks of Washington, D C , and the Committee on Motion Pictures, with Dr Archibald D Campbell of Montreal, Canada, as chairman, have completed preliminary plans for their respective sections of the meeting and are ready to issue application blanks for space and time These blanks are designed to facilitate the work of the committees in selecting and presenting exhibits and films of the greatest value and to make it easy for the applicants to present a complete description of their proposed displays They will be sent on request by the business office of the American Congress at 24 West Ohio Street, Chicago 10, Illinois, and, when completed, go directly to the chairman of the committee involved

The members of the Scientific and Educational Exhibit Committee working with Dr Parks are Dr Miguel V Falsia of Buenos Aires, Sir Eardley Holland of London, Dr Mortimer N Hyams of New York, Dr Alice F Maxwell of San Francisco, Dr Lawrence M Randall of Rochester, Dr Jorge de Rezende of Rio de Janeiro, Dr Erik Rydberg of Copenhagen, Dr Donald G Tollefson of Los Angeles, and Dr Frank E Whitacre of Memphis

The members of the Committee on Motion Pictures working with Dr Campbell are Dr David N Barrows of New York, Dr Willard R Cooke of Galveston, Dr Samuel A Cosgrove of Jersey City, Dr Carl Henry Davis of Wilmington, Dr Ludwig A Emge of San Francisco, Dr Albert W Holman of Portland, Dr Edmundo G Murray of Buenos Aires, and Dr Robert A Ross of Durham

Plans for the holding of the Congress at the Hotel Statler, New York City, from May 14 to 19, 1950, are progressing satisfactorily An important program of scientific papers and exhibits is being developed, and a large attendance is likely For further information apply to the headquarters office, 24 West Ohio Street, Chicago 10, Illinois

NECROLOGY

[Continued from page 1472]

William Henry Specht, M D , sixty-seven, who retired in 1947 after practicing in New York City for many years, died on May 19 of a heart attack while on a fishing trip in Canada A graduate of Cornell University Medical College in 1906, Dr Specht had his office in New York City before retiring two years ago to live in Germantown He was formerly a member of the New York County and State Medical Societies and the American Medical Association

Charles Francis Spencer, M D , of Ossining, believed to be the oldest alumnus of New York University Medical School, died on May 23 at the age of ninety-two Dr Spencer was graduated from New York University in 1882, after having completed a three-year medical course in two years After leaving college he joined the staff of Manhattan State Hospital on Ward's Island, as assistant superintendent, and then served with the New York City Health Department until 1912 as head of the sanitary inspection division His chief duty with the department was the suppression of epidemics, and he received considerable attention in his fight against smallpox He practiced medicine in New York City before his retirement

Randolph West, M D , fifty-eight, died on May 20 at his home in the Bronx A graduate of the College of Physicians and Surgeons, Columbia University, in 1917, Dr West interned at Presbyterian Hospital and did graduate work in chemistry at the University of Chicago In 1922 he returned to Presbyterian Hospital, where he was attending physician, and joined the Columbia Medical School's faculty as professor of medicine

As a specialist in internal medicine for twenty-seven years, Dr West devoted much effort to the study of anemia and, in 1942, after years of independent research, joined a team of chemists and biologists seeking the therapeutic element which checks pernicious anemia. The element was finally isolated in 1947 as Vitamin B_{12} and Dr West was the first to demonstrate its efficiency

For many years Dr West was editor of the *Journal of Clinical Investigation* and the author of many scientific papers He was chairman of the anti-anemia board of the U S Pharmacopeia and a Fellow of the American College of Physicians Dr West was a member of the Association of American Physicians, the American Society of Clinical Investigation, the New York Academy of Medicine, the Society for Experimental Biology and Medicine, the Harvey Society, the New York County and State Medical Societies, and the American Medical Association

For his work in developing Vitamin B_{12} Dr West was to have received the first Goldberger Award of the Nutrition Foundation, given for outstanding contributions to clinical nutrition

A REALLY DELICIOUS STOUT

. . . WITH SPECIAL QUALITIES

★ Since the introduction of MACKESON'S MILK STOUT to America, this internationally-known brew has met with the most favorable acceptance by leading members of the medical profession ★ Brewed from the finest British malt, MACKESON'S MILK STOUT is a product of the highest grade in respect to purity and body It differs from ordinary stout in that it contains the carbohydrates of the purest dairy milk which increase its protein content and nutritive value — and to which its distinctive mellowness and very palatable flavor are due ★ These special qualities of MACKESON'S MILK STOUT have long been recognized as beneficial in all cases where a stout may be recommended on medical grounds

LEG ULCERS

the DAXALAN-DOME-PASTE BANDAGE TECHNIQUE

AS INTRODUCED BY DR WILLIAM M. COOPER Director Department of Peripheral Vascular Diseases—New York Polyclinic Medical School and Hospital.

This technique is based on a 3 point program—

1. Reduction of dermatitis with wet dressings of DOMEBORO TABS *(BUROW S SOLUTION)*
2. Combat local infection and stimulate healing with thick application of DAXALAN in the center of the ulcer and surrounding areas
3. Overcome venous insufficiency stasis and edema by wrapping DOME PASTE BANDAGE around the entire leg to supply compression.

DOCTOR! You may now prescribe SOOTHING Modernized Simplified Fresh and Stable BUROW S SOLUTION 1 20 in four forms DOMEBORO Tablets Packets Powder Ointment

WHEN OBESITY IS A PROBLEM

Clinicians have long noted that the forward bulk of the heavy abdomen with its fat-laden wall moves the center of gravity forward As the patient tries to balance the load, the lumbar and cervical curves of the spine are increased, the head is carried forward and the shoulders become rounded Often there is associated visceroptosis Camp Supports have a long history among clinicians for their efficacy in supporting the pendulous abdomen The highly specialized designs and the unique Camp system of controlled adjustment help steady the pelvis and hold the viscera upward and backward There is no constriction of the abdomen, and effective support is given to the spine Physicians may rely on the Camp-trained fitter for precise execution of all instructions

If you do not have a copy of the Camp "Reference Book for Physicians and Surgeons", it will be sent on request

TRASENTINE-PHENOBARBITAL

A powerful antispasmodic with selective action avoiding undesirable side effects

Effective relief of visceral spasm is generally obtained with Trasentine or Trasentine-Phenobarbital By its selective action, Trasentine avoids the undesirable side effects of dryness of the mouth and pupillary dilatation frequently produced by belladonna or atropine These advantages have caused physicians to prescribe more Trasentine and Trasentine-Phenobarbital than probably any other brand of antispasmodic

- Average adult dose is one or two tablets 3 or 4 times daily as required.

TRASENTINE PHENOBARBITAL — Tablets (yellow) contain 50 mg Trasentine hydrochloride with 20 mg phenobarbital, in packages of 40, 100 and 500

TRASENTINE — Tablets (white) of 75 mg, in bottles of 50 and 500, also suppositories of 100 mg, and ampuls of 50 mg

How mild can a cigarette be?

DOCTORS REPORT

In a recent test of hundreds of people who smoked only Camels for 30 days, noted throat specialists, making weekly examinations, reported

"NOT ONE SINGLE CASE OF THROAT IRRITATION DUE TO SMOKING CAMELS!"

SMOKERS REPORT

"I MADE MY OWN PERSONAL 30-DAY TEST! NOW I KNOW—CAMELS ARE THE MILDEST, BEST-TASTING CIGARETTE I EVER SMOKED!"

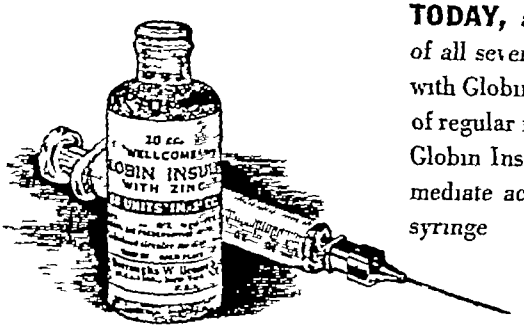
GLOBIN INSULIN



'B.W.& CO.'

was developed to fill the "need for an insulin with activity intermediate between that of regular insulin and that of protamine zinc insulin"[1]

IN 1939, Reiner, Searle and Lang described a new "intermediate acting" insulin

IN 1943, after successful clinical testing, the new substance was released to the profession as 'Wellcome' brand Globin Insulin with Zinc 'B W & Co'

TODAY, *according to Rohr and Colwell,* 'Fully 80% *of all severe diabetics can be balanced satisfactorily*"[2] with Globin Insulin 'B W & Co'—or with a 2 1 mixture of regular insulin protamine zinc insulin *Ready to use* Globin Insulin 'B W & Co' provides the desired intermediate action without preliminary mixing in vial or syringe

'B.W & CO —a mark to remember

In 10 cc vials U-40 and U-30

The psychosomatic price

The tensions of modern living demand a price that is frequently gastrointestinal injury, occasionally peptic ulcer The prevention and cure of peptic ulcer embrace the application of hygienic, psychiatric, dietary, and therapeutic techniques to this problem

Logically, therapy should include the administration of materials which will tend to reduce the acidity of the gastric content without producing alkalosis or other undesirable effects Coincidentally, a demulcent effect should be sought to coat the ulcerated surfaces and protect them from erosion *Lederle* research has found that a casein, low in sodium, high in calcium, in appropriate form when given by mouth will accomplish these ends and provide the patient with prompt symptomatic relief

CONSTANT INSPECTION for BABY'S PROTECTION

Our inspectors examine every single ten-gallon can of fresh milk as it comes from the dairy, but this is only the beginning of the tests we apply to Nestlé's Evaporated Milk.

From herd inspection to examination of the filled cans, careful controls at every step of production assure you that Nestle's milk is of good quality, uniform in composition, safe for even the tiniest baby

Antirachitic protection is assured by the addition of 400 U S.P units of genuine vitamin D_3 to each pint of Nestlé's milk—the first evaporated milk so fortified.

CONSTANT INSPECTION for BABY'S PROTECTION

Our inspectors examine every single ten-gallon can of fresh milk as it comes from the dairy, but this is only the beginning of the tests we apply to Nestlé's Evaporated Milk.

From herd inspection to examination of the filled cans, careful controls at every step of production assure you that Nestle's milk is of good quality, uniform in composition, safe for even the tiniest baby

Antirachitic protection is assured by the addition of 400 U S.P units of genuine vitamin D_3 to each pint of Nestle's milk—the first evaporated milk so fortified.

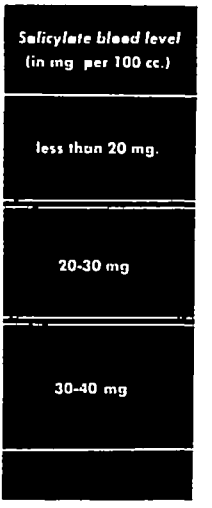
AN IMPORTANT NEW MILESTO

in the Therapy of Arthritic Affections



The "cure of [rheumatic fever]", agree most authoritative sources,[2,3,5,6] "depends not only on reaching, but also on maintaining a high plasma salicylate level "[5] The correlation between such blood levels and symptomatic improvement is graphically shown in the table at the right [6]

Pabalate—latest product of Robins' research —now helps to achieve and maintain *higher salicylate blood levels on lower salicylate dosage*

This is made possible by the combination in Pabalate of non-toxic para-aminobenzoic acid with sodium salicylate As visualized in the chart at the lower right,[4] para-aminobenzoic acid (itself an active antirheumatic)[7] manifests a reciprocal action with salicylates when administered concurrently—sharply increasing the blood salicylate levels (under constant salicylate dosage),[1,4] and in turn having its own blood levels effectively enhanced [4]

The clinical significance of this synergistic relationship represents an important advantage in the therapy of arthritic affections Pabalate 'Robins'—a strictly ethical preparation— is available at (or may be secured by) all leading pharmacies

A. H ROBINS CO, INC., RICHMOND 20, VA.
Ethical Pharmaceuticals of Merit since 1878

indications Rheumatoid arthritis, acute rheumatic fever, fibrositis, gout, osteo-arthritis.

dosage Two or three enteric coated tablets every three or four hours, without sodium bicarbonate.

formula Each enteric coated tablet contains
Sodium salicylate, U S P (5 gr), 0.3 Gm.,
Para aminobenzoic acid (as sodium salt), (5 gr), 0.3 Gm.

supplied In bottles of 100 and 500 enteric coated tablets.

For high salicylate blood levels on low salicylate dosage—

Pabalate®

Pabalate tablets are enteric coated to prevent gastric irritation and insure optimal toleration

a constant shield in allergy

In the treatment of allergy with antihistaminics it is essential to assure the patient a continuous, uniformly high degree of protection. Too rapid excretion or detoxification of the drug inevitably leads to a fluctuating, unreliable status, alternating between full protection and complete vulnerability. Chlorothen, Whittier, is distinguished pharmacologically by its prolonged action. Clinically, therefore, each dose may be relied upon to maintain a greater protective effect for a longer dosage interval—a constant defensive shield against allergens.

ULTRACAIN *therapy*

Wherever an anesthetic, bacteriostatic and fungistatic ointment is indicated—

ULTRACAIN® OINTMENT effects prompt and prolonged relief in pruritus, ulcers, fissures, ulceration, abrasions, burns and in mucocutaneous lesions.

It is significantly free from allergizing side-effects.

Write for literature.

MEAT...

And This Protein Era

"Today we are in the protein era "* This terse but meaningful statement, made by an outstanding authority in a recent review on the progress of nutrition, reflects an accomplishment of utmost significance.

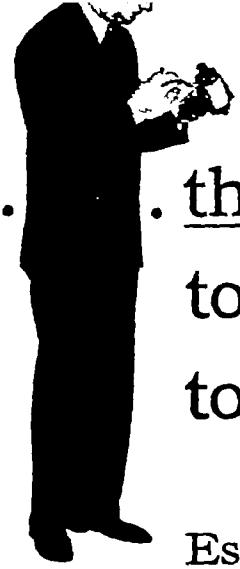
This résumé of modern nutrition concepts shows convincingly that the recognition of the vital role of protein in health and disease ranks among the great advances of medicine

The therapeutic use of a high protein dietary has revolutionized the prognostic outlook in many hepatic diseases formerly considered resistant to treatment

The use of high protein dietaries has resulted in a gratifying reduction of surgical morbidity and mortality, made possible by systematic presurgical nutritional build-up of the patient Through this same approach, wound healing and general recovery are greatly promoted

In nephritis and nephrosis, at one time considered absolute contraindications for animal protein in the dietary, the use of protein in liberal amounts can significantly reduce mortality and decidedly improve the clinical condition

The benefits derived from high-protein nutrition in pregnancy and lactation are diversified and far-reaching, embracing both mother and offspring For this reason, a generous extra serving of meat, given daily as a routine measure, has been strongly recommended as a means of improving the health of mother and child



Meat is rightfully regarded as an outstanding protein source It is notably rich in protein The protein of meat is biologically complete, capable of satisfying all protein needs of the body from childhood to old age And, particularly important in disease, the excellent digestibility of meat gives virtual assurance that its protein and other valuable nutrients become available for utilization

*McLester, J S Protein Comes Into Its Own, J A M A *139* 897 (April 2) 1949

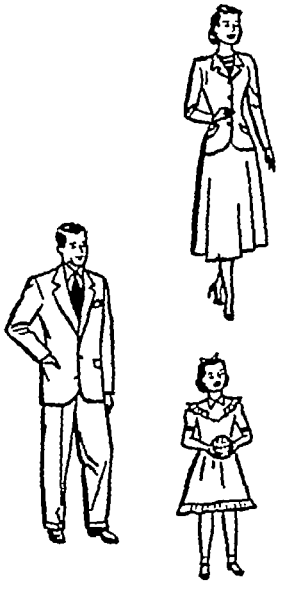
. . . . . this is the way to give phenobarbital to children

Eskaphen B Elixir is the ideal phenobarbital preparation for children because
Its fluid form makes it easy to take
Its good taste makes it pleasant to take
Its mild and calming action is supplemented by the tone-restoring effect of thiamine

And this is important

Parents who "know all about phenobarbital"—and might be upset at the idea of giving a "sleeping mixture" to their children—don't know you are prescribing phenobarbital when you write

Eskaphen B Elixir



the delightfully palatable combination of phenobarbital and thiamine

Smith, Kline & French Laboratories, Philadelphia

Each 5 cc teaspoonful of ESKAPHEN B ELIXIR contains phenobarbital ¼ gr thiamine 5 mg.

Scabies, until recently regarded as a disease of poverty or uncleanliness, today is known to be found in all walks of life This highly contagious parasitic infestation not infrequently escapes detection, hence the possibility of its presence must always be kept foremost in mind when a red, punctate, inflamed pruritic eruption presents itself

In the eradication of scabies Kwell Ointment, containing 0 5% gamma benzene hexachloride in a vanishing cream base, represents a significant advance in therapy A single course of treatment consisting of one or two applications effects a cure in more than 90% of patients Its action is prompt, positive, and is not burdened by secondary dermatitis or relapse

Kwell Ointment is available on prescription in 2 oz and 1 lb jars at all pharmacies

PROTEIN

The incidence of mild protein deficiencies in children, predisposing toward infections and edema, is reported[1,2] much greater than generally realized. Infant and adolescent requirements—not only for tissue repair and maintenance, but also for growth—are much higher than in adulthood.[3] To insure adequate protein intake in infancy, DRYCO—Borden's high protein infant food—is ideally suited as a basis for formula building. It furnishes *all the essential amino acids*. Its low fat content minimizes gastro-intestinal upsets due to fat intolerance, while its intermediate carbohydrate content lends itself for prescription with or without added carbohydrate. Quickly soluble in cold or warm water, DRYCO contains adequate vitamins A, B_1, B_2 and D, plus essential milk minerals.

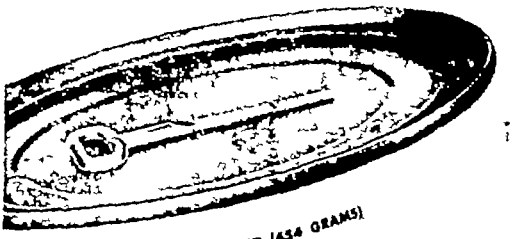
The "Custom Formula" High Protein Infant Food

Quiets Smooth-Muscle Spasm



The chief effect of papaverine is relaxation of all smooth muscle without interference with normal contractions Many conditions associated with smooth-muscle spasm have been benefited by papaverine therapy Prescribe Papaverine Hydrochloride, Lilly, for relief of vascular spasm associated with coronary occlusion, angina pectoris, and peripheral and pulmonary embolism, for bronchial spasm and accompanying allergic conditions, such as asthma, and for visceral spasm, as in ureteral, biliary, and gastro-intestinal colic Tablets and ampoules are available on prescription at all retail and hospital pharmacies

Lilly

THE HIGH-PROTEIN INFANT FOOD

The incidence of mild protein deficiencies in children, predisposing toward infections and edema, is reported[1,2] much greater than generally realized. Infant and adolescent requirements—not only for tissue repair and maintenance, but also for growth—are much higher than in adulthood.[3] To insure adequate protein intake in infancy, DRYCO—Borden's high protein infant food—is ideally suited as a basis for formula building. It furnishes *all the essential amino acids*. Its low fat content minimizes gastro-intestinal upsets due to fat intolerance, while its intermediate carbohydrate content lends itself for prescription with or without added carbohydrate. Quickly soluble in cold or warm water, DRYCO contains adequate vitamins A, B_1, B_2 and D, plus essential milk minerals.

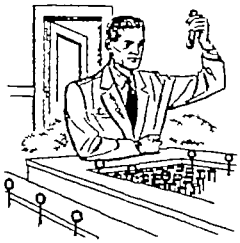
The Unending Struggle

The apparently ill-advised but persistently hopeful Mr Oscar Ewing, F S A. chief, and his mimetic followers still claim that 325,000 deaths out of the 1,400,000 which occur annually in the United States are preventable "Use of the annual number of deaths as a measure of health progress," says the *J.A M A*, editorially, "is fallacious Obviously this reduction cannot be accomplished in an increasing and aging population, because the total number dying each year in any nation depends on the number of people, their ages, and the death rate per thousand at each age Nor can the annual number of deaths be kept from actually increasing during the coming years "[1]

Surely we are faced with an increasing population and an aging group Twenty years from now the number of deaths in our aging population may well be 1,500,000 to 1,600,000, the length of life doubtlessly will be greater, and the mortality rate for each age will be lower than now Use of the annual number of deaths as a measure of health progress is fallacious "Health progress and the number of deaths each successive year are simply two different ideas," the editorial points out



What this has to do with the question of national compulsory health insurance is slightly less than clear "We have the knowledge," says Mr Ewing in "The Nation's Health—a Ten-Year Program," "to prevent 325,000 deaths each year" So what?

Invariably advocates of state medicine, or socialized medicine use these figures as the opening gambit in debating the question "Should We Have National Compulsory Health Insurance?"

The inference to be drawn is that medicine is not doing its job, that in some unexplained way it is withholding from the people available knowledge which would make unnecessary the deaths of 325,000 persons annually The absurdity of this intended inference seems obvious But are nonmedical people likely to question the assertion? Mr Ewing apparently did not, since he made it in what we may assume to be good faith in his report to the President.

HEARTS THAT NEED YOUR HELP AND OURS

The incidence of heart disease continues to increase as the average span of life is lengthened The problem is being attacked on several fronts Delicate instruments of diagnosis, better preventive measures, and improved surgical techniques have been devised Knowledge of the physiology of the heart and vascular system is increasing Useful new drugs have been introduced, and more are being developed

Specialists in this field at the Lilly Research Laboratories are placing major stress upon the medical approach to this problem With crystalline digitoxin and newer diuretic drugs, many victims of advanced heart failure, who formerly would have been considered beyond treatment, are now relieved of symptoms Papaverine hydrochloride makes possible the symptomatic relief of coronary occlusion, angina pectoris, and certain types of vasospastic disease Even though the fundamental disease condition remains, life may be prolonged and made more useful and pleasant

Lilly

MANY SPECIALISTS SERVE THE MEDICAL PROFESSIO

it reports, in relation to the construction of Veterans Administration Hospitals, "The Federal government is assuming uncalculated obligations without any understanding of their ultimate cost, the lack of necessary professional manpower to carry them out, or their adverse effect upon the hospital system of the country" And again, "(there is a) pattern of duplication of physical facilities, waste of scarce medical personnel, and unwarranted construction of new facilities—all resulting primarily from the lack of a central plan for federal medical care"

We are among those skeptics who view governmental intervention whether fiscal or managerial in evolutionary developments as the last full measure of defeat We require, for instance, to be shown *on the record*, specifically, where, when and how government has provided better, quicker, and cheaper medical service than private initiative has produced Medical care for the armed services? What, actually, did it cost? Could the taxpayer stand for that high cost service short of war necessity?

All the talk in the world will do little to alter the fact that national health insurance as a function of the social security program would probably prove to be the most costly experiment ever undertaken and head the list of uncalculable obligations which might easily lead to bankruptcy of the nation

Beauty or Bouquets? Some days ago we noted these headlines in the New York *Times*—"Hospitals Provide Facials and Waves"[1]

At first our reaction was one of indignation At these times, in particular, when every effort must be made to enlist the public in voluntary hospital insurance, to bring down in every possible way the cost of medical care, was not this increased service, with its considerable cost, an unconscionably unjustifiable frivolity?

Fortunately, before we had had time to commit ourselves to paper, the words of a wordly minded college friend came floating up from our subconscious, "Never," he was wont to say, "propose to a girl until you have seen her eating an orange at a football game"

In our early days in the hospital we had often amplified his sage advice to read, "Never propose to a girl until you have seen her coming out of ether"

[1] New York Times March 5 1949

This amplification, after more years of married life than we care to acknowledge, we instantly rejected Men and women are poor creatures at best, and they are entitled to whatever defenses—camouflage, if you care to use the harsher term—their self-respect persuades them to erect Fortunately for us—as should be at intervals the lot of every surgeon—we had recently undergone an operation The first glance into the mirror afterwards was of far greater importance than any information as to the healing of our wound With what gratitude did we welcome the agonies of inexpertly wielded razor that removed the horrid stubble from our shapely chin!

Whereas for a woman (we quote from an authority—one who suffered operative complications and almost died) the situation is much worse "Flowers," says she, "for the period when you may be going to die and don't care if you are They bring beauty and a breath of friendship into your state of dreamy unreality There must still be, among the living, people who care for you, and that faint perfume that mitigates the odor of the institution promises perhaps a tolerable life that may still be worth holding on to

"But when you have turned the corner, when your nurse's look of desperate anxiety has turned to one of more or less patient boredom, and one, bolder than the rest, puts a mirror in your hand, then is the moment that is the supreme trial of a woman's soul Can it be possible that you really look like that? Is survival worth the trouble? Will any man ever welcome home that pale and ravaged face, that dank hair, those ridged and lifeless looking finger nails? It is a crisis"

Isn't it better to hold yourself as if you felt well, rather than to hold yourself as if you felt ill? Every time you see yourself in a shop window you get a positive, not a negative reflection If you have the strength of mind and body to hold yourself erect when you feel terrible, what is it but camouflage? Or call it dignity, if you prefer

Help out the suffering woman Give her a facial Wave her hair Manicure her hands Pull her one foot out of the grave by making her look an object that her husband may yet gaze upon without repulsion Do it now Forestall the undertaker

Yes, we are all for the beauty parlor at the bedside It does not increase the cost

Allegedly "preventable" accidental deaths are also dragged in by Mr Ewing and his mimes in the same red herring technic We agree with the writer of the editorial that,

> If the Administrator's estimate of "preventable" accidental deaths is intended as a plea for more and better safety and accident prevention measures, every one will commend the Administrator for bringing an important matter to the attention of the public Bulletin 64, "What Is the Leading Cause of Death? Two New Measures," by the Bureau of Medical Economic Research of the American Medical Association, has shown that accidental deaths cut off more working years from the lifetime of the American people than any one natural cause of death "Fatal accidents" is the number one destroyer of the working years of life The National Safety Council, the millions of plant safety workers, the traffic policemen, and even the school children on patrol duty would doubtless welcome the aid and help of the vast Federal Security Agency in the prevention of accidents Physicians realize that a comprehensive scheme for an extensive reorganization of the nation's medical services could not eliminate 40 per cent, or 40,000, of the annual 100,000 accidental deaths

While physicians realize the absurdity of the claim that 40,000 of these accidental deaths could be prevented by Mr Ewing's proposed "extensive reorganization of the nation's medical services," it should be held in mind that the claim is not addressed to physicians but to the public, and again by inference the profession is made to appear negligent

The misleading use of the U S draft rejection figures is another instance of assertion by indirection that the profession of medicine could have salvaged more, that rejections would have been fewer under government-controlled medicine The fact that the same medical personnel would have had to do the salvaging of the possible six per cent of those rejected who, according to Rowntree, might have benefited by prior medical treatment is utterly ignored

That these matters have little or nothing to do with the actual health of the nation seems to have no weight with the proponents of national compulsory health insurance, many of them otherwise intelligent non medical persons One is compelled to assume, reluctantly, either that they honestly have fallen for their own propaganda, have charmed themselves with their own music, or knowingly are selling these gold bricks on the theory that the end justifies the means

Current Editorial Comment

Uncalculated Obligations Discussing public financing of medical education, research, health, and medical care, the *New England Journal of Medicine* comments on an address by Dr Allen M Butler delivered to the Suffolk District Medical Society as presenting "astutely and temperately the arguments in favor of compulsory health insurance "[1]

Says the *Journal* editorially

> The fact that in 1946 the Government spent $1,200,000,000 for health and medical care is taken by Dr Butler as "a measure of the failure of philanthropy and private charity to meet the needs" Presumably the expenditures of the Veterans Administration are included in this figure, but aside from this no estimate is available as to how much of the colossal outlay was necessary, or how wisely and economically it was made If this vast sum was expended with caution and judgment, and with due regard to conservation of the country's resources, then the employment of some part of it is certainly acceptable so far as present concepts are concerned This applies especially to those allocations having to do with public health, with the care of communicable disease and mental illness, and to a considerable degree with research There is, however, a line, indistinct as it may be, beyond which governmental encroachment may be justly considered as dangerous in that it may jeopardize the quality of medical care There is still occasion, in our imperfect society, for skepticism regarding the efficiency of government methods

ADVANCES IN PHYSICAL MEDICINE

From the Department of Rehabilitation and Physical Medicine
New York University College of Medicine

Howard A Rusk, M D , Director

The Role of Therapeutic Exercises in the Treatment of Low Back Pain

In many clinical "low back" cases thorough workup and x-ray studies frequently fail to establish an anatomic diagnosis In this group and in many "osteoarthritic" cases, where muscle deficiencies seem to be responsible for at least part of the complaint of the patient, it pays to submit the muscles to a few simple tests

We can gauge the strength of the back muscles by placing the patient face down, hips resting on a pillow The examiner holds the back and legs on the table and asks the patient to raise his trunk with hands locked behind neck If the patient can raise his chest to a horizontal position and hold this position to the count of 10, his "upper back muscles" are graded as 10 and considered normal Then the examiner holds chest and hips of patient and asks him to raise both legs to horizontal, again for ten seconds This gives an estimate of "low back" strength Ten seconds can be considered normal

The patient should then lie supine and raise both legs to an angle of about 30 degrees above the table, holding this position with legs straight to the count of 10 This gives normal rating of "lower abdominals" "Upper abdominal" strength is determined by asking the patient to lock hands behind neck, holding his ankles, and asking him to sit up If he can accomplish this from 180 degrees (i e , a flat position) grading is 10, or normal If he needs assistance and can take his full weight only from a 45 degree position he is rated as 5 (half of normal) The degrees in between are rated by how close they come to the 180 degree, or flat, position The same test can be made with knees flexed and feet placed close to buttocks In this position the hip flexors are eliminated and "straight abdominals" tested

Next, hamstring length is measured by passively raising a straight leg and measuring the angle between leg and table at the point at which the contralateral hip or knee shows movement, thus indicating that the hamstring length of the examined side has been exhausted Normal figures should be around 80 degrees Total length of back muscles and hamstrings can be measured by having the patient stand up straight and attempt to touch the floor with the tips of the fingers Touching the floor should be possible for a normal person

Frequent deviations in these figures can be found, but it may be assumed that a person who does not conform to these standards has a functionally poor back and may be subject to back strain sooner than a person whose back conforms to these minimal standards

The results of these tests can be written in a formula which permits easy evaluation of test results Assuming "upper back muscle strength" of 10 and "lower" 10, abdominal muscle strength of "upper" 10, "lower" 10 and "straight" 10, and back muscle-hamstring length—touching floor 90/90 degrees, or a normal back, the result can be written as follows

$$B\,\frac{10}{10}\,A\,\frac{10}{10}\,10$$

$$BH—t$$

$$H\,\frac{90}{90}$$

Where the respective figures fall below normal, weakness or muscle tightness is present

Therapeutic exercises are prescribed according to these relative weaknesses or

of hospital care The hospital gets 10 per cent of the costs of beauty treatments which the patient would have had at home, anyway Let friends send flowers for the first week and beauty treatments for the second When the husband's desperate anxiety is assuaged, let him convert his liquor and his cigaret money to the same purpose Such treatment is not adding to the cost of hospital care It is putting the gilt onto the gingerbread of every woman's life—married or single

From Personal Experience Take it from one who has suffered

"Don't make me laugh! I've lived under these schemes" So says Dorothy Thompson, referring to her experiences with socialized medicine in Germany, France, Great Britain, and Austria

Every practitioner of medicine in the State of New York has had experience with workmen's compensation Most of us will admit that a workingman injured in the line of duty deserves compensation during the resulting period of disability Most of us will admit that in most cases the law has worked well

But what has the average doctor to say about the workings of the law?

That it gives him an immense amount of paper work to do

That he often has great difficulty in getting his patients who are receiving compensation to go back to work

That he has made enemies on all sides If he is honest in his conviction that his patient is cured, and says so, his patient, who should be grateful, damns him to his face, and blackens his reputation, so that few other injured workingmen will, under their right of free choice of physician, seek his services

If his judgment inclines the other way and he is prone to keep the patient too long under his fostering care, the insurance company is against him In spite of "free choice" he finds that his supply of compensation cases is dwindling, which might be due to underground influence

If he is the best and most conscientious surgeon in the State, if every factor combines to work with him for good, the fee schedules set for him by the State are so absurdly inadequate that he would prefer to do such work as charity, if he could afford to

If he is the accommodating type, who "goes along" as the phrase is, he knows that compensation cases will continue to come to him, and he will soon learn to steer the middle course that on the one hand pays him for his diathermy machine and his masseuse and on the other tells him just when to stop treatment because the insurance company thinks the patient has had enough

Under such a system the patient is either over- or undertreated

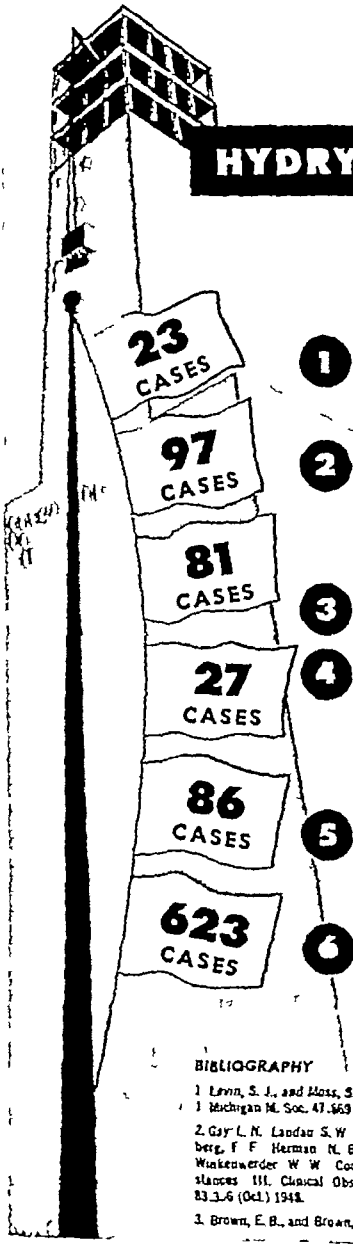
Under such a system the doctor is either under- or overpaid

We believe that our remarks, in regard to New York State at least, are applicable.

How would you like to have such a condition made nation wide?

Doctors and Atomic Energy The births of many of the physical sciences were assisted by ingenious physicians The study of gases and the measurement of heat were once the exclusive province of medical doctors Current electricity had its inception in medical research on nerves There is good precedent, therefore, that nuclear physics, the youngest of the physical sciences, should also benefit by the attention of the medical profession Medicine was probably the first science to be recognized as such, obviously because it had a vital and practical importance to every citizen

Rear Admiral Strauss points out that the development of atomic energy poses to medicine new and fearful questions[1] Radiation hazards on a large scale are a threat to life, health, and reproduction Both in theory and in practice how to handle it safely is a medical problem To make atomic energy useful, we must convert an advance in pure science to practical ends The conversion must clear three hurdles prejudice, tradition, and special interests These interests are the government departments, the industrial laboratories, and the universities Each of these should be maintained, but in a way to promote the early and intelligent development of the benign uses of atomic energy



The handicaps are government inflexibility, impossibility of adequate reward of industry's key personnel, and the tendency of universities to disregard quick practical returns, while continuing large expendi-

THE EVIDENCE IS OVERWHELMING

"markedly benefited"[1]
"% benefited . . . 73"[2]
"relief obtained"[3]
"definite relief"[4]
"relieved 56 per cent"[5]

1 "The results in hay fever with Hydryllin were very striking Twenty of twenty three seasonal hay fever patients (86 9 per cent) were markedly benefited, receiving relief varying from 50 to 100 per cent "[1]

2 '% benefited 73 "[2] In table 1 it is shown that Hydryllin benefited 73 per cent of ninety seven patients with seasonal and perennial allergic rhinitis.

3

"Symptom	Number of patients	Relief Obtained 100%	75%	50%	20%	0
Hay Fever	81	39	12	11	5	14"[3]

4 ' In a group of hay fever cases, 14, or 52 per cent, obtained definite relief (50 to 100 per cent amelioration of symptoms) with Hydryllin. In some cases relief followed immediately after the first use of the drug, but in other cases it was necessary to increase the dose to three to six tablets daily "[4]

5 ' Hydryllin relieved 56 per cent of 86 patients. "[5]

AND IN ASTHMA

6 ' In the asthmatic cases, both those with asthma due to pollen and those having asthma from other sources, the figures of the effectiveness of the drug are more impressive than those of other antihistaminics. '[6]

HYDRYLLIN TABLETS contains

Diphenhydramine	25 mg
Aminophyllin	100 mg

HYDRYLLIN with *Racephedrine Hydrochloride*
Each tablet contains:

Hydryllin	125 mg
Racephedrine Hydrochloride	25 mg

HYDRYLLIN ELIXIR (4 cc. = ½ Hydryllin tablet)

HYDRYLLIN COMPOUND (cough syrup preparation)

muscle shortnesses A formula of

$$B\,\frac{10}{10}\,A\,\frac{5}{10}\,0$$

$$BH—5$$

$$H\,\frac{60}{60}$$

would indicate a back with weak abdominal muscles and tight hamstring muscles This back would benefit by strengthening exercises for the abdominal muscles and, at a later stage, by back muscle and hamstring stretching

Examination of large numbers of these "muscular backs" reveals certain types of trunk weaknesses and certain relations with the pelvic tilt that are very interesting If these different types of relative muscle deficiencies are followed it becomes apparent why no exercise "system" can answer all the questions, but why individual testing and prescription is necessary

It is of utmost importance to give the patient a limited but well-supervised exercise program The weak patient may have to start five-minute periods several times a day and gradually work up to one or two half-hour periods a day to obtain satisfactory results The exercises must be performed under supervision of the doctor or therapist and, unless this is done regularly, at least two or three times a week, and followed up by daily home exercises, no results can be expected

The following figures may illustrate that a meticulous exercise approach will yield results Of a total of 143 patients 92 (or 65 per cent) were found to be "muscular backs" Of these patients 71 (77 per cent) treated with therapeutic exercises were relieved of their complaints and conformed to normal muscle test standards, 11 (12 per cent) complained of occasional pain or did not quite conform to normal standards, and 10 (11 per cent) were not relieved

The acute painful low back is an entirely different chapter and should never be subjected to the above muscle tests Here the relief of pain, due to painful muscle spasm, should be the first step Surface anesthesia (ethyl chloride spray) and extremely mild exercises should be given Exercises should consist of the patient lying on one side, pulling the upper leg toward his chest, bringing it down again, extending it, and repeating that movement two or three times on each side The above movement should be accompanied by spraying the painful area with ethyl chloride Spray should be intermittent and skin should never be "frozen" The patient should repeat these exercises two or three times every half hour

Only after this acute stage is passed and complete workup has been given should muscle tests be performed Deep tenderness of the muscles and surface tenderness of the skin require respective approach by massage The presence of "osteoarthritis," together with relative muscle deficiencies and frequently born out by "jelling" pain, requires "scattered" exercises (i e, simple movements performed very frequently during the day) aiming at preventing recurrence of this "jelling" pain

OBSTETRIC ANESTHESIA

A CRITICAL APPRAISAL OF SPINAL ANALGESIA AND ANESTHESIA FOR OBSTETRICS

BARNETT A GREENE, M D , Brooklyn, New York

(From the Departments of Anesthesiology, Adelphi, Unity, and Brooklyn Women's Hospitals)

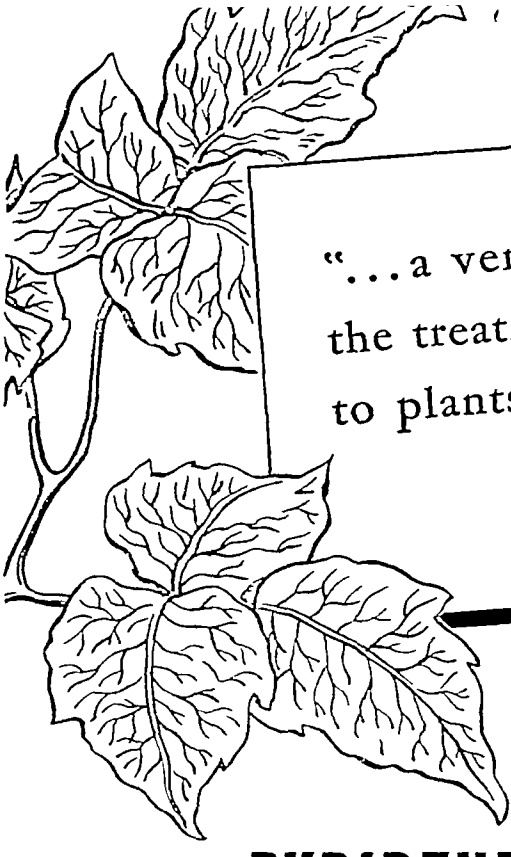
SPINAL analgesia and anesthesia for vaginal or abdominal delivery is on the crest of a new wave of popularity Following Lemmon's innovation of fractional spinal anesthesia in 1940, many who have feared single-dose technics for cesarean section now use fractional spinal anesthesia. As a result of Hingson's development of continuous caudal analgesia from Lemmon's method, caudal analgesia for labor and vaginal delivery has become popular in many communities Because the caudal technic is often difficult, sometimes impossible, and occasionally contraindicated by local anatomic features, spinal analgesia has become popular as a substitute for caudal

Spinal anesthesia for obstetrics is destined to fall again into disfavor, as has happened twice in the past, unless it is employed with the fine precision and judgment necessary to obtain its undeniable advantages without its well-known and feared complications and disadvantages

The purpose of this report is to describe my experience with spinal anesthesia in obstetrics with special emphasis on those measures which I believe are necessary for its safe and uncomplicated use I have personally administered more than 27,000 spinal anesthesias for all cases including 520 for cesarean section. Our group of anesthesiologists has given over 2,000 spinals for labor and vaginal delivery

Spinal is still the most dangerous method of obstetric anesthesia, as De Lee and Greenhill have long taught That is true, however, only for those who are ignorant of the physiologic changes produced by spinal anesthesia, who are lacking in clinical judgment of a patient's ability to tolerate those changes, and who are unprepared to correct abnormalities of respiration and circulation during anesthesia and delivery The factor which has contributed most to the tragic history of spinal anesthesia is the ease with which it can be performed by anyone, e g , a nurse at one hospital in Brooklyn In the hands of an anesthesiologist who is experienced, skillful, and alert with spinal anesthesia, it is a safe and valuable method

Skill with spinal anesthesia is an art There are some who do not learn to choose the patient and the particular method wisely, who are not adept and facile in technic, and who are not quickly observant of danger signs These anesthetists should avoid spinal anesthesia in obstetrics



During the past twelve years, I have tried most of the drugs and technics recommended in the literature As a result I have adapted certain basic principles and practices for spinal anesthesia for obstetrics

"Saddle Block" Anesthesia

Every spinal anesthesia for obstetrics, whether for vaginal or abdominal delivery, must rise to the thoracic ninth segmental areas, the level of the umbilicus, if analgesia of uterine "pains" or surgery is to be obtained "Saddle block" is a misnomer and misleading for a spinal analgesia of this height A "saddle block" proper covers only the anus, rectum, genitals, and the inner aspects of the thighs, the area innervated by the sacral nerves [1] This point is stressed so that any one who attempts to relieve obstetric pain should approach it with the same attention and safeguards that one must use for spinal anesthesia for cesarean section.

A true "saddle block" is excellent just for the terminal phase of a vaginal delivery I have long

Presented at the 143rd Annual Meeting of the Medical Society of the State of New York, Buffalo Section on Anesthesiology May 4 1949

"...a very valuable adjunct to the treatment of dermatitis due to plants, especially

POISON IVY..."[1]

PYRIBENZAMINE cream or ointment

Applied locally, Pyribenzamine hydrochloride usually gives prompt and prolonged relief from itching in dermatitis venenata due to poison ivy, oak or sumac.

Pyribenzamine has also been found to give relief to the majority of patients with other itching dermatoses, "particularly atopic dermatitis and pruritus ani"[2]

"In many instances the local skin conditions are, of course, more rapidly and more completely eradicated by the combined topical and oral administration of this drug"[1]

man, especially in surgical or obstetric patients, obtained with due regard for the patient's water balance and the disturbances created by the experimental effort to measure spinal fluid formation The key to preventing and treating the postspinal headache is in knowing and utilizing the fact that the restoration of cerebrospinal fluid volume reduced by leakage is directly proportional to the degree of body hydration [13,14]

These considerations led us to try consecutive series of vaginal deliveries under spinal analgesia using 20-, 22-, 24-, and 26-gauge needles In each needle gauge group, some patients were specially hydrated by mouth, and others were permitted to take fluids as desired

The 20-gauge series had 17 patients 41 per cent developed headache, 23 per cent had severe headaches This series had to be cut short because the obstetricians objected to its continuation

The 22-gauge series had 211 patients 17 per cent developed headache, 6 per cent of all patients had severe headaches Of the 108 patients who were specially hydrated, 10 per cent had a headache, and only one was severe, of the 93 patients not hydrated, 26 per cent had headache, and 6 per cent of patients had it in severe form

The 24-gauge series contained 341 patients, 5 per cent of all patients complained of headache, but only 1 per cent had severe headache The specially hydrated 149 patients had a headache incidence of 2 per cent with only one severe headache, the nonhydrated group of 192 patients had an incidence of 8 per cent with 2 per cent of patients affected with severe headache

The 26-gauge series contained 116 patients, 3 per cent of all patients developed a headache None was severe Two instances occurred in the 21 nonhydrated patients Of the 95 hydrated, "26-gauge needle" patients the only headache (and that was mild) occurred in the migrainous wife of a physician who insisted on the spinal analgesia rather than a caudal which had precipitated a violent and protracted headache after her first delivery

These trials have convinced us that the practical solution of the headache problem in spinal analgesia for vaginal delivery is to use a 26-gauge lumbar puncture needle and to hydrate the patient by forcing her to drink ten glasses of fluids, approximately 2,500 cc , during each of the first three days postpartum If dehydration or blood loss has been marked or the lumbar puncture has been unavoidably performed with a 22-gauge or larger needle, we advise, in addition to oral forced fluids, an infusion of one liter of isotonic glucose in water, or more if indicated Posterior pituitary extract, ten units twice a day for two days, is a valuable aid in retaining body water and hydrating the central nervous system

Fractional Spinal Anesthesia

Fractional spinal anesthesia has revived the popularity of spinal for cesarean section, because it enables the surgeon or anesthetist to secure an analgesic level gradually with minimal dosage and to maintain it as long as desired The fractional method is no safer than the individual using it I know of an unpublished death following the injection of 60 mg of procaine hydrochloride by the fractional method applied by a resident in anesthesiology to a young cesarean patient exhausted by prolonged labor Failure to restore and control the peripheral circulation with fluids and ephedrine sulfate were the causes of this preventable death

I have used the fractional method in only 42 cesarean sections although I have applied it in over 500 major, general surgical cases The anesthesiologist who is expert in the use of single-dose technic with heavy Nupercaine rarely needs the fractional method The fractional method is reserved for the cesarean patient who should receive spinal anesthesia because of great abdominal distention, marked obesity, or a serious contraindication to general anesthesia but who is also a poor risk for the ordinary technic because of cardiac failure or depleted blood volume The patient with a defective circulation of peripheral or central origin is more safely injected with the anesthetic drug only after the needle or catheter has been inserted, she has returned to lie on her back, and an infusion has been started running with certainty through a large gauge intravenous needle Fractional spinal is also especially useful when analgesia is desired to begin immediately after a decision has been made to section a patient in active, painful labor, and one must wait an uncertain or appreciable period of time for the operation to begin.

Fractional spinal analgesia has been recommended for labor and vaginal delivery, but such use is seriously limited by the high incidence of severe postpuncture headache [15,16] Occasionally I have used it when continuous caudal analgesia was not feasible and a single-dose technic was contraindicated by uncertainty regarding the course and state of labor

Knowledge of the conduct of labor and vaginal delivery under fractional spinal analgesia is valuable when a caudal needle has inadvertently punctured the subarachnoid space during the attempt to use Hingson s method Instead of withdrawing the caudal needle as advised in most publications, the caudal needle should be permitted to remain in the subarachnoid space and

used it for this purpose as recommended in 1928 by Pitkin and McCormack and by Cosgrove [2,3] For this purpose procaine hydrochloride crystals, 50 to 100 mg in spinal fluid to form a 5 per cent hyperbaric solution, is still the preferred drug The early enthusiasts erred seriously on two counts, first in recommending it for all cases, including those with a ruptured uterus or ectopic pregnancy, and secondly, in encouraging its use by any one with "no greater knowledge than that of doing a lumbar puncture (and) by the operator himself, thereby eliminating the necessity of an anesthetist" [2] Gleeson in Jersey City and Fraser in Canada have also applied terminal spinal anesthesia for vaginal delivery for more than a decade with good results [4,5]

Use of Vasopressor Drugs

Ephedrine sulfate or an analogous vasopressor drug is an important factor for safety in all cases of spinal anesthesia, but it is indispensable in obstetrics because of the rapid decompression of the abdomen and the significant blood loss associated with delivery Even before delivery, the parturient's blood pressure seems abnormally labile in response to spinal analgesia We administer 50 mg ephedrine sulfate or 5 mg neosynephrine hydrochloride hypodermically ten minutes before every spinal anesthesia unless hypertension is present In that case, the vasopressor is withheld, to be injected intravenously as soon as the blood pressure falls below 100 mm Hg systolic and as often thereafter as needed It is regrettable to note reports based on a relatively few cases in which a prespinal vasopressor is deliberately omitted [6,7] It is especially deplorable for the commercial literature, from which so many beginners learn obstetric spinal analgesia, to state that "it is not necessary in saddle block (with Nupercaine)" and to recommend such time-wasting and questionably effective measures as oxygen inhalation and elevation of the legs as the first with which to treat hypotension. The failure to use a vasopressor correctly or promptly has been the cause of several recent maternal deaths in our community

Prolonged Spinal Anesthesia

Prolonged spinal analgesia for labor and delivery has been developed as a substitute for the continuous caudal method when a patient cannot benefit by a caudal because of anatomic difficulties or local contraindications We have come to prefer spinal analgesia to caudal for any normal parturient whose delivery can be reasonably expected within four hours

The anesthesiologist using spinal analgesia must become familiar with the diagnostic criteria of labor if he wishes to avoid "hanging up a labor" or spending his time uneconomically Spinal analgesia for labor, because it cannot be interrupted, requires more precise diagnosis of presentation, station, and cervical dilatation than does continuous caudal analgesia.[8] Spinal is, therefore, not our first choice for the patient whose course of labor cannot be predicted accurately Spinal analgesia is avoided when the patient is prone to headache For the cardiac or the preeclamptic, caudal is preferable to spinal because the former is more gradual in onset and more controllable in duration

Nupercaine (1 200) is our selection for spinal analgesia required for more than one hour We have been using it in general surgery for the past eight years according to the technic of Romberger, and, therefore, we have learned that it is not especially prone to producing neurologic complications or headache, contrary to some reports [4,9,10] Furthermore, we have found that Nupercaine, unlike Pontocaine or Metycaine, is not likely to rise to an unduly high level In fact, Nupercaine (1 200) is unreliable for upper abdominal surgery unless a deliberate effort is made to obtain a high level by the use of large volumes of diluent and the Trendelenburg position

We start spinal analgesia for labor according to the same indications for the initiation of continuous caudal analgesia [8] By combining 1 cc of Nupercaine (1 200) and 1 cc 10 per cent glucose with 1 cc of 5 per cent ephedrine sulfate or 1 1,000 epinephrine hydrochloride, we have regularly obtained analgesia for labor and delivery lasting four hours Where analgesia is desired for only two hours, a vasoconstrictor is omitted from the mixture of 1 cc Nupercaine (1 200) and 1 cc 10 per cent glucose In 700 spinal analgesias for labor we have had to repeat the spinal or add a supplementary anesthesia in only eight cases, four of these were instituted by residents in training

Postspinal Headache

Postspinal headache is the most common and annoying complication of spinal anesthesia for obstetrics We have practically solved this problem by utilizing the "leakage" explanation It is unfortunate that this etiology is not more widely accepted, but anyone familiar with the multitude of supporting observations accumulated in the monographs of Wolff and Thorsen is bound to accept the leakage theory [11,12]

The great difficulty with the "leakage" explanation has been the inability to understand how spinal fluid could be deficient in volume, even though leakage has occurred, if spinal fluid is formed in the large quantities reported in textbooks The fact is that there are no reliable data on the rate of formation of spinal fluid in

an, especially in surgical or obstetric patients, ɔtained with due regard for the patient's water ılance and the disturbances created by the exɪrimental effort to measure spinal fluid formaɔn. The key to preventing and treating the ɜstspinal headache is in knowing and utilizing .e fact that the restoration of cerebrospinal ıd volume reduced by leakage is directly proɔrtional to the degree of body hydration [13 14]

These considerations led us to try consecutive ries of vaginal deliveries under spinal analgesia ıng 20-, 22-, 24-, and 26-gauge needles In .ch needle gauge group, some patients were speılly hydrated by mouth, and others were perıtted to take fluids as desired

The 20-gauge series had 17 patients 41 per cent developed headache, 23 per cent had severe headaches This series had to be cut short because the obstetricians objected to its continuation

The 22-gauge series had 211 patients 17 per cent developed headache, 6 per cent of all patients had severe headaches Of the 108 patients who were specially hydrated, 10 per cent had a headache, and only one was severe, of the 93 patients not hydrated, 26 per cent had headache, and 6 per cent of patients had it in severe form

The 24-gauge series contained 341 patients, 5 per cent of all patients complained of headache, but only 1 per cent had severe headache The specially hydrated 149 patients had a headache incidence of 2 per cent with only one severe headache, the nonhydrated group of 192 patients had an incidence of 8 per cent with 2 per cent of patients affected with severe headache

The 26-gauge series contained 116 patients, 3 per cent of all patients developed a headache None was severe Two instances occurred in the 21 nonhydrated patients Of the 95 hydrated, "26-gauge needle" patients the only headache (and that was mild) occurred in the migrainous wife of a physician who insisted on the spinal analgesia rather than a caudal which had precipitated a violent and protracted headache after her first delivery

These trials have convinced us that the practical solution of the headache problem in spinal analgesia for vaginal delivery is to use a 26-gauge lumbar puncture needle and to hydrate the patient by forcing her to drink ten glasses of fluids, approximately 2,500 cc , during each of the first three days postpartum. If dehydration or blood loss has been marked or the lumbar puncture has been unavoidably performed with a 22-gauge or larger needle, we advise, in addition to oral forced fluids, an infusion of one liter of isotonic glucose in water, or more if indicated Posterior pituitary extract, ten units twice a day for two days, is a valuable aid in retaining body water and hydrating the central nervous system

Fractional Spinal Anesthesia

Fractional spinal anesthesia has revived the popularity of spinal for cesarean section, because it enables the surgeon or anesthetist to secure an analgesic level gradually with minimal dosage and to maintain it as long as desired The fractional method is no safer than the individual using it I know of an unpublished death following the injection of 60 mg of procaine hydrochloride by the fractional method applied by a resident in anesthesiology to a young cesarean patient exhausted by prolonged labor Failure to restore and control the peripheral circulation with fluids and ephedrine sulfate were the causes of this preventable death

I have used the fractional method in only 42 cesarean sections although I have applied it in over 500 major, general surgical cases The anesthesiologist who is expert in the use of single-dose technic with heavy Nupercaine rarely needs the fractional method The fractional method is reserved for the cesarean patient who should receive spinal anesthesia because of great abdominal distention, marked obesity, or a serious contraindication to general anesthesia but who is also a poor risk for the ordinary technic because of cardiac failure or depleted blood volume The patient with a defective circulation of peripheral or central origin is more safely injected with the anesthetic drug only after the needle or catheter has been inserted, she has returned to lie on her back, and an infusion has been started running with certainty through a large gauge intravenous needle Fractional spinal is also especially useful when analgesia is desired to begin immediately after a decision has been made to section a patient in active, painful labor, and one must wait an uncertain or appreciable period of time for the operation to begin.

Fractional spinal analgesia has been recommended for labor and vaginal delivery, but such use is seriously limited by the high incidence of severe postpuncture headache [15 16] Occasionally I have used it when continuous caudal analgesia was not feasible and a single-dose technic was contraindicated by uncertainty regarding the course and state of labor

Knowledge of the conduct of labor and vaginal delivery under fractional spinal analgesia is valuable when a caudal needle has inadvertently punctured the subarachnoid space during the attempt to use Hingson s method Instead of withdrawing the caudal needle as advised in most publications, the caudal needle should be permitted to remain in the subarachnoid space and

used it for this purpose as recommended in 1928 by Pitkin and McCormack and by Cosgrove [2,3] For this purpose procaine hydrochloride crystals, 50 to 100 mg in spinal fluid to form a 5 per cent hyperbaric solution, is still the preferred drug The early enthusiasts erred seriously on two counts, first in recommending it for all cases, including those with a ruptured uterus or ectopic pregnancy, and secondly, in encouraging its use by any one with "no greater knowledge than that of doing a lumbar puncture (and) by the operator himself, thereby eliminating the necessity of an anesthetist" [2] Gleeson in Jersey City and Fraser in Canada have also applied terminal spinal anesthesia for vaginal delivery for more than a decade with good results [4,5]

Use of Vasopressor Drugs

Ephedrine sulfate or an analogous vasopressor drug is an important factor for safety in all cases of spinal anesthesia, but it is indispensable in obstetrics because of the rapid decompression of the abdomen and the significant blood loss associated with delivery Even before delivery, the parturient's blood pressure seems abnormally labile in response to spinal analgesia We administer 50 mg ephedrine sulfate or 5 mg neosynephrine hydrochloride hypodermically ten minutes before every spinal anesthesia unless hypertension is present In that case, the vasopressor is withheld, to be injected intravenously as soon as the blood pressure falls below 100 mm Hg systolic and as often thereafter as needed It is regrettable to note reports based on a relatively few cases in which a prespinal vasopressor is deliberately omitted [6,7] It is especially deplorable for the commercial literature, from which so many beginners learn obstetric spinal analgesia, to state that "it is not necessary in saddle block (with Nupercaine)" and to recommend such time-wasting and questionably effective measures as oxygen inhalation and elevation of the legs as the first with which to treat hypotension. The failure to use a vasopressor correctly or promptly has been the cause of several recent maternal deaths in our community

Prolonged Spinal Anesthesia

Prolonged spinal analgesia for labor and delivery has been developed as a substitute for the continuous caudal method when a patient cannot benefit by a caudal because of anatomic difficulties or local contraindications We have come to prefer spinal analgesia to caudal for any normal parturient whose delivery can be reasonably expected within four hours

CONTINUOUS CAUDAL ANESTHESIA IN OBSTETRICS

Observations of Results in Twelve Thousand Cases

JACOB HERZLICH, M D , Brooklyn, New York

(From the Beth-El Hospital)

IN OBSTETRICS a suitable pain-relieving agent is sought which will be safe for the mother and baby and will not interfere with the progress of labor Stoeckel in 1909 used caudal anesthesia in obstetrics to relieve labor pains with fair results [1] It was also tried by Cathelin in 1900 for surgical procedures involving the perineum [2] However, not until Hingson and Edwards described the method of continuous caudal anesthesia has there been a satisfactory obstetric analgesic and anesthetic [3]

We have used this method with the malleable needle technic as the method of choice at the Beth-El Hospital since February, 1943, and have applied it in over 12,000 instances We have found its utilization facilitates cervical dilatation, permits normal descent of the presenting part, diminishes blood loss, and has no untoward effect on the parturient mother or the fetus

Methods for control of pain during labor have heretofore rested in the hands of the obstetrician When labor was well established, the administration of drugs to obliterate the memory of pain, whether by mouth, subcutaneously, by rectum, or intravenously was relatively simple Although the same expert obstetric judgment is needed to determine the existence of favorable conditions for the administration of continuous caudal anesthesia, the technic of its administration need not necessarily be part of the duties of the obstetrician An anesthetist specially trained in caudal anesthesia assumes the responsibility for its administration

After properly introducing the needle, the anesthetist must be on the alert The judicial administration of the anesthetic fluid in fractional doses, testing for accidental puncture of the dura, obliteration of pinpricking pain in the perineal, vulva, symphyseal and suprasymphyseal areas, the appearance of rectal relaxation, the commencement of warmth in the lower extremities, and the cessation of uterine cramps, are some of his immediate duties In addition, he must be in constant attendance to add more anesthetic fluid when the pains return or the level of anesthesia falls much below midway between the symphysis and umbilicus He continues to watch the variations in the blood pressure, follows the progress of cervical dilatation and descent of the presenting part, and helps the patient turn from side to side Finally, when the patient is ready for delivery and the last dose adequate for completion of the delivery is administered, he removes the needle and transports the patient to the delivery room While delivery is in progress, he is constantly in attendance and does not leave until the third stage of labor is completed and the pelvic floor is repaired The cooperation and teamwork between the anesthetist and obstetrician is necessary for the safe and effective conduct of labor with caudal block as the obstetric anesthesia

Thus, the anesthesia department partakes in the management of the obstetric patients during labor and delivery At the Beth-El Hospital we have provided the obstetricians with continuous attendance by an anesthetist

The anesthetist partakes in the management of the patient undergoing a surgical procedure The expectant mother, while in labor, is accorded the same undivided attention of an expert anesthetist as if she were undergoing a surgical operation

The anesthesia department integrates its work with the obstetric division Three anesthetists are assigned daily Thus, one anesthetist is always available during the twenty-four hour period

Successful results in caudal anesthesia depend on personnel employed in its administration. The anesthetist administering this type of anesthesia in obstetrics must not only be a good anesthetist but must have a good knowledge of obstetrics He should not have to depend on the obstetrician to inform him when a caudal is to be started He should be fully capable of determining position and descent of the fetus and dilatation of the cervix At Beth-El Hospital, all the anesthetists on the staff have had a thorough training in obstetrics as well as in caudal anesthesia

Poor results in caudal anesthesia have resulted from superficial and inadequate training given to anesthetists and obstetricians This training has been as short as a two-week course This brief period does not give the obstetrician sufficient knowledge of anesthesia, nor does it give the anesthetist a thorough background of obstetrics

Caudal anesthesia in obstetrics has been condemned by many physicians because of isolated cases where complications have arisen during the

Presented at the 143rd Annual Meeting of the Medical Society of the State of New York, Buffalo Section on Anesthesiology May 4 1949

the prepared caudal solution should be intermittently injected in appropriately small doses, e g, 15 to 45 mg Metycaine

When fractional spinal anesthesia is indicated, I prefer the Tuohy technic with the ureteral catheter to the Lemmon malleable needle The latter requires a special support for the back, sometimes the needle slips out of place while the patient is being turned, occasionally and inexplicably the anesthesia is very slow in developing Most important, however, is the fact that the Lemmon technic may cause permanent neurologic damage by the malleable needle bending into and traumatizing the cord or nerve roots One death and two permanent major neurologic sequelae have occurred in three unpublished cases handled by experienced anesthesiologists The Tuohy technic has not been associated with such damage and seems much less likely to be able to cause it

Fractional spinal anesthesia is objectionable for the ordinary cesarean delivery because the required large dural puncture is followed by a 40 per cent incidence of postspinal headache in our use of the catheter method, unless special measures are taken to prevent headache [16]

Single Dose Technic

The single-dose technic of spinal analgesia for cesarean section is preferred in 95 per cent of our patients It is simpler, quicker, and more dependable The safety of the single-dose technic for the great majority of patients in careful hands is just as great as that of the fractional method, but with careless or inexpert management a single-dose method is more dangerous than a fractional technic My personal experience with the single-dose method for cesarean sections includes more than 450 cases There has not been a single maternal or fetal death or permanent complication attributable to the anesthesia

For cesarean section, I use the same technic as for vaginal delivery except that I prefer to weight the 1 cc of 1 200 Nupercaine with 50 to 75 mg of procaine hydrochloride crystals dissolved in 1 to 1 5 cc spinal fluid The procaine-Nupercaine combination enables the surgeon to start promptly, without the delay and uncertainty that attends the waiting period associated with a glucose-Nupercaine mixture

The spinal puncture needle for the single-dose method of spinal anesthesia for cesarean section need be only a 22 or 24 gauge inasmuch as the infusions which cesarean patients regularly receive minimize the headache problem when the needle is not of large gauge.

Every cesarean patient has an infusion started immediately after the anesthetic is injected In poor risk cases the infusion is begun before the spinal Control of the circulation is essential and is secured by ephedrine sulfate or neosynephrine sulfate administered hypodermically ten minutes before the spinal, unless contraindicated by hypertension or cardiac failure Vasopressor drugs needed after the onset of spinal anesthesia should be given intravenously

Care must be taken to avoid severe hypertension produced by the inadvertent addition of the vasopressor effect of hypodermic or intrauterine injected pituitrin or intravenous ergotrate, ordered by the obstetrician, to that of the ephedrine or neosynephrin used by the anesthetist Cerebral complications have resulted from the acute hypertension so induced [17]

Summary

Spinal anesthesia has reached a new and greater peak of popularity in obstetrics as a result of the use of Nupercaine-glucose for analgesia in labor and vaginal delivery and the development of fractional spinal anesthesia for cesarean section. The technics of single-dose and fractional methods of anesthesia for abdominal and vaginal delivery are discussed and compared, their indications and complications are described

The leakage theory of postpuncture headache is explained and utilized in correlation with the importance of hydration in influencing the restoration of normal cerebrospinal fluid volume and pressure Headache following spinal analgesia for vaginal delivery is practically prevented by the use of a 26-gauge needle and increased hydration by oral fluids

due to excessive fat pads, atresia of the sacral hiatus, distortion and malpositions of the bony landmarks in the sacrococcygeal area, or faulty technic We also included in this group the instances where spinal fluid was obtained during the initial insertion of the needle

Three of our five localized infections occurred in our first 250 cases Undoubtedly, this was due to the deposition of anesthetic fluid subcutaneously, on the erroneous assumption that the needle was in the caudal canal The infections were noted late in the postpartum period and were treated by wide incision and drainage There were 28 instances of dural puncture Spinal fluid was noted on introduction of the needle, and the procedure was discontinued We had eight instances of inadvertent dural puncture This accident was noted, despite absence of spinal fluid on original insertion of the needle and after the first dose of 8 cc of 1½ per cent Metycaine was given The location of the needle in the subarachnoid space was recognized by early sudden cessation of pain, inability to move the legs, and marked early rectal relaxation In each case, the needle was withdrawn, and the patient was placed in Fowler's position to prevent the anesthesia from rising, and the patient was delivered under this inadvertent spinal anesthesia These instances emphasize the importance of fractional administration of the first 30 cc of Metycaine

High level caudal analgesia was noted in 15 cases One was due to a faulty valve which allowed the reserve solution to siphon into the caudal canal In order to avoid this difficulty the reserve solution should be placed on a level lower than the caudal canal The other high levels developed despite slow administration of the solution and only when indicated, i e , when the pains returned or the level of anesthesia fell much below the umbilicus This complication was probably due to the small capacity of the epidural space The patients in whom high level anesthesia developed became restless and anxious Some complained of precordial pressure, numbness in the upper extremities, dizziness, difficulty in respiration, and nausea and vomiting There was a moderate fall in blood pressure in these cases (20 to 30 mm) This condition was combated by elevation of the head and trunk to permit downward gravitation of the anesthetic fluid Ephedrine sulfate ⅜ grain was given by hypodermic Oxygen inhalation was given to the few patients that showed some respiratory embarrassment These symptoms lasted only a short time, labor continued, and delivery was effected without any further incidents To reduce the incidence of high level caudal anesthesia, we have limited all subsequent injections to 10 cc instead of the usual 20 cc

We have had no nerve injuries in any of our patients who received this method of analgesia We have had one broken needle which was easily removed There were no instances where the needle caused injury to any of the neighboring organs or to the fetus because of false passage of the needle

Contraindications to the use of caudal anesthesia, such as unengaged presenting part, transverse presentation, antepartum bleeding, localized infection in area, excessive fat pad in area, bony malformations, and poliomyelitis, are to be considered When the presenting part is floating or not definitely engaged, especially in cephalic presentation, pelvic delivery may be in doubt It is, therefore, advisable to wait until cephalopelvic adequacy is assured by additional trial of labor In transverse presentation, internal podalic version may be needed to terminate labor To accomplish this, one needs a relaxed uterus, and, therefore, it is best to use general anesthesia A similar procedure may be needed in management or termination of labor in cases of antepartum bleeding where either placenta previa or abruptio placenta is encountered

Caudal anesthesia should not be given to patients having a pilonidal cyst or sinus Similarly, when an excessive fat pad is present, this form of anesthesia should not be attempted, unless the landmarks can be palpated We do not use this form of analgesia in lower extremity muscular atrophy following poliomyelitis

A high incidence of operative deliveries results from the use of any form of obstetric analgesia The increase, however, is limited to low forceps or outlet forceps The use of low forceps and episiotomy on all primipara has become routine, even when no analgesia is used during labor

We have also noticed a greater incidence of major operative deliveries, such as manual rotation, forceps rotation, and mid forceps This is probably due to our policy of early interference We firmly believe that, when the cervix is completely dilated and a short waiting period does not correct the malposition, delivery should be undertaken soon to prevent soft tissue damage and fetal embarrassment Bill has long advocated a watchful waiting policy during the first stage of labor in these malpositions but insists that early correction and delivery after complete cervical dilatation is beneficial both to mother and infant [5]

Breech extraction or spontaneous breech delivery can be performed with ease under this form of analgesia However, when the breech is high in the pelvic and where manipulation to break up a frank breech may be necessary, it is not advisable to use continuous caudal anesthesia for delivery Uterine relaxation is necessary during

administration of caudal anesthesia I attribute the majority of these poor results to poor judgment and insufficient training

The question that has often arisen among patients is, "Am I a suitable candidate for caudal anesthesia when I give birth?" According to a statement made by Dr Hingson in 1944, about 40 per cent of the women delivered in well-staffed maternity hospitals present contraindications prohibiting the successful use of continuous caudal analgesia [4] He further points out that 70 per cent of American births are eliminated from this type of anesthesia because it is not a procedure to be used in the home and the poorly-staffed hospital He further states that if every hospital in this country used continuous caudal analgesia in every suitable case, only 12 per cent of the parturient women would be treated by this method

The contraindications which make up 40 per cent of hospital deliveries, according to Dr Hingson, are as follows easy and rapid labor, 10 per cent, deformities of the sacrum, 10 per cent, fear, 10 per cent, obesity, 3 per cent, local infection, 2 per cent, and anemia, placenta previa, premature separation of placenta, disproportion, and sensitivity to anesthetic agent, 5 per cent

When I started the caudal service at Beth-El Hospital, I found these statistics to be fairly accurate, but at present there is a marked deviation Of all our vaginal deliveries approximately 90 per cent receive caudal anesthesia

The 10 per cent of the cases that do not receive caudal anesthesia are made up as follows

1 Easy rapid deliveries—4 per cent Our maternity cases usually enter the hospital early in labor, and the anesthetist is always present to administer the caudal immediately if necessary

2 Deformities of the sacrum—not more than 1 per cent In 1943, when I first started to administer caudal anesthesia in obstetrics, I found that over 20 per cent of the patients had deformities of the sacrum This high percentage gradually decreased as time elapsed, and at present it is rare to find a case in which the caudal canal cannot be entered

3 The element of fear does not exist among the patients at our hospital Our obstetricians instill confidence in the safety of caudal anesthesia to the mother and baby Consequently, the woman in labor is free from worry and fear She is cooperative and helpful However, obstetricians at other institutions have not given such confidence to their patients A flagrant example to be cited is one in which a well-known obstetrician, upon being asked by his patient whether she would receive caudal anesthesia during labor, exclaimed, "How would you like to have a long, sharp needle jabbed mercilessly into your spine?" Thus, we can see that fear of caudal anesthesia is created by physicians who are not thoroughly familiar with this type of anesthesia

4 Obesity—Approximately 1 per cent of our patients do not receive caudal anesthesia due to their marked obesity

5 Local infection and disease—approximately 3 per cent of our patients do not receive caudal anesthesia due to local infection or disease

It has been maintained that caudal anesthesia should be administered only in well-staffed maternity hospitals This contention is wrong At the smaller hospital, where there is inadequate hospital personnel, it would be advantageous to the expectant mother to receive caudal anesthesia and thus be closely watched by the anesthetist In this way, early discovery of a fetal distress might be made In addition, the anesthetist is present at time of delivery and thus insures the well-being of the newborn should resuscitation be necessary

We have applied this form of anesthesia and are at present reporting our observations and results in the first 12,000 cases (Tables 1 and 2) There was a total of 433 patients where the anesthesia was classified as a failure The partial failure were in cases that had painful uterine contraction during the running of the continuous caudal anesthesia, but actual delivery and repair were free from pain Many of our partial failures were encountered in patients who had received previous caudal anesthesia We attribute these secondary failures to thickening and fibrosis of the connective tissue attachments between the inner wall of the vertebral canal and the dural sac, thus preventing the upward diffusion of the drug and resulting in ineffective blocking of the eleventh and twelfth dorsal nerves The other partial failures may be due to (1) unusually large caudal canal, (2) open roof, (3) wide dural space, or (4) dislodgement of the needle The complete failures may be

INHALATION ANESTHESIA IN OBSTETRICS

KENNETH G JAHRAUS, M D , Eggertsville, New York

(From the Deaconess Hospital of Buffalo)

DURING the past one hundred years inhalation analgesia and anesthesia have played an important role in the relief of pain associated with childbirth In 1847, shortly after the discovery of anesthesia, ether and chloroform were introduced in the conduct of labor by Sir James Y Simpson The use of anesthesia in obstetrics became widely recognized and gained impetus following the use of chloroform in the delivery of Queen Victoria's seventh child in 1853 Gradually, other agents were added, and, with increased knowledge, improved apparatus, and new technics, inhalation analgesia and anesthesia became pleasanter, safer, and more versatile Although new caudal, spinal, and block technics have been advocated and popularized in recent years, inhalation anesthesia is employed in the bulk of obstetric deliveries today It is generally simpler, easier, and quicker in application and safe in the varying demands of obstetrics

Pharmacologic Characteristics

Let us consider some of the pharmacologic characteristics of the various inhalation agents that are most frequently employed in obstetric anesthesia These consist of the volatile liquids ether, chloroform, and vinethene, and the gases nitrous oxide, ethylene, and cyclopropane

Ether, which is generally considered the safest of all agents, is unpleasant to inhale, irritating to the respiratory passages, and usually too slow in action when used intermittently for pain relief If the pain is of the explosive type, it is almost useless unless a state of near-anesthesia is maintained with a resulting decrease in uterine contractions and an increase in nausea, operative interference, and fetal apnea However, ether is very safe, requires the least experience for its successful administration, and is very useful when combined with one of the gaseous agents for added relaxation in operative deliveries or cesarean section

Chloroform is sweet, pleasant, smooth, quick, and effective in action When used as an analgesic, it most closely duplicates nitrous oxide Transmission from the analgesic to the anesthetic state and the reverse is accomplished smoothly and quickly Administration should be careful, steady, and with adequate oxygenation Chloroform's toxic effects, especially on the liver and heart, have generally condemned its use Experimentally, the effect of chloroform on the liver may be minimized or eliminated entirely by volatilization in oxygen, a high carbohydrate diet the day preceding its administration, and by the proteins methionine and, to a lesser extent, cystine when given before or within four hours of chloroform anesthesia Anoxia, starvation, and high fat diets increase the toxic effect Pregnancy, of itself, does not offer any special protection in so far as the liver is concerned

Vinyl ether or vinethene is a slightly irritating, extremely volatile liquid which has been used to a limited extent in obstetrics Its use has been generally restricted to one-half hour due to its toxic effect on the liver The combination of 25 per cent vinyl ether with 75 per cent ethyl ether was suggested by Bourne, McDowell, and Whyte as a practical solution to the problem of tremendous waste from rapid volatilization which occurs when vinyl ether is used alone [1] Excessive mucus is sometimes an undesirable complication

The narcotic gases, nitrous oxide, ethylene, and cyclopropane, provide the anesthesiologist with an agent of low toxicity which can rapidly provide pain relief during labor with control from moment to moment These gases are apparently unaltered in the body and are eliminated unchanged The various organs like the liver and kidneys are exposed to a minimum of functional disturbance, and damage to the various tissues does not occur unless these gases are administered with inadequate amounts of oxygen The passage from analgesia to anesthesia and the reverse may be accomplished quickly so that the maximum effect of a minimum amount of the drug is readily obtainable Obvious limitations to the administration of narcotic gases during a long labor are the amount of apparatus and personnel involved, as well as the time and economic factor

Nitrous oxide is a slightly sweet gas, nonirritating and nonflammable, and is our best agent for providing obstetric analgesia It is pleasant and safe and may be given continuously or intermittently for pain relief Its use by the continuous method with oxygen and air has been described and recommended by Sword [2] Usually it is given intermittently in concentrations of 50 to 100 per cent depending upon the rapidity, severity, and duration of pain perception by the patient Where surgical anesthesia is necessary,

Presented at the 143rd Annual Meeting of the Medical Society of the State of New York, Buffalo Section on Anesthesiology May 4 1949

such a procedure, and with this method of analgesia the powerful uterine contractions continue at frequent intervals and interfere with the maneuver

We found that there was no delay in initiation of respiration in the newborn when this form of analgesia was used The infant in many instances emits a cry even before delivery is complete This is particularly useful in managing the fetus in premature labor Labor continues painlessly under this form of analgesia until full dilatation is reached The perineum is relaxed, and the abdominal muscles are out of play, thus eliminating bearing down pains No pressure on the head is present, thus avoiding possible intracranial injury Delivery by early low forceps is possible, and no inhalation anesthesia is necessary for the termination of labor The premature fetus is spared the narcotizing effects for relief of pain during labor and the additional narcosis of a general anesthesia during termination of labor

Summary and Conclusions

1 Relief of pain during labor by obliterating the memory of pain has been tried by many obstetricians with varying success

2 Absolute requirements for the safe and efficient administration of continuous caudal anesthesia are adequate trained personnel, cooperation between anesthetist and obstetrician, and proper organization for the administration of the anesthetic

3 The anesthetist must be in constant attendance during the entire time of the administration of anesthesia and during delivery and repair There must be a separation of duties and responsibilities of the anesthetist and obstetrician, although each must have a working knowledge of the other's experience

4. Continuous caudal anesthesia was attempted in 12,000 cases Complete relief of pain was obtained in 11,567 patients or 96 4 per cent

5 The complications encountered are enumerated and their management and prevention discussed Contraindications to the use of continuous caudal analgesia are emphasized in order to avoid these complications

6 The entire labor is markedly shortened Cervical dilatation is facilitated, thus shortening the first stage, the second stage is frequently delayed and must be terminated by low forceps, the third stage is definitely shortened and uncomplicated The entire labor and delivery can be accomplished under this form of analgesia.

7 There is no delay in initiation of respiration in the newborn Fetal distress is very rare It is extremely beneficial to the premature during labor and delivery

8 The absolute freedom from pain during labor, the lack of interference with the processes of labor, the beneficial effect on the fetus, and the ability to complete the delivery under this form of anesthesia convinces us that continuous caudal anesthesia is the method of choice to relieve pain during childbirth

MIRACLE DRUGS GREATLY REDUCE DEATHS FROM MENINGITIS

A method of penicillin therapy new in the treatment of meningitis, the crippling and formerly highly fatal inflammation of membranes covering the brain and spinal cord, has reduced the death rate from one type of the disease from 62 to 36 per cent, say four Washington, D C , doctors The doctors—Harry F Dowling, Lewis K. Sweet, Harold L Hirsh, and Mark H Lepper—make their report in the March 19 issue of the *Journal of the American Medical Association*

In a series of 22 patients with pneumococcic meningitis who were given large injections of penicillin in the muscles every two hours, the death rate was 36 per cent. Twelve of these patients also received sulfa drugs, however, sulfa drugs do not seem to be necessary when large doses of penicillin are used, the doctors point out In an earlier series of 66 patients treated with the older method of a smaller amount of penicillin given systemically plus repeated injections of penicillin into the cavity that surrounds the brain and spinal cord, the death rate was 62 per cent Among 434 patients with meningococcic meningitis, the most frequent type of the disease, the death rate was only 8.9 per cent. These patients were treated with sulfa drugs and, in some cases, with the new penicillin therapy

obstetric anesthetics It was used particularly in those deliveries requiring extreme relaxation of the uterus such as podalic version and extraction or where birth was imminent and anesthesia started in bed or on the cart The amount of chloroform used is generally less than one ounce, and it is administered with the open technic, a Yankauer mask being used and held at least one finger breadth away from the face The eyes are protected with a folded towel The patient's pulse, color, respiration, and eye signs must be watched carefully Although we are mindful of its toxic effects, this agent has been safe and dependable in our hands In a survey of maternal mortality from 1941 to 1945 in Erie County by the Maternal Mortality Committee of the Buffalo Obstetrical Council, it was estimated that in over 50,000 chloroform anesthetics there had been only three deaths

In the 51 cesarean sections cyclopropane anesthesia was used for 42 and spinal anesthesia for nine Small amounts of ether or curare were used with the cyclopropane when additional relaxation was required Fetal loss consisted of three stillborns and one newborn death, none of which were related to anesthesia The stillborns included two cases of premature separation of the placenta with severe hemorrhage and one ruptured uterus The newborn death was a hydrocephalic baby which lived several hours

Pituitrin is not used because of its undesirable action on the coronary arteries, especially when the heart is under the effect of a drug such as cyclopropane or chloroform Such drugs as pitocin or the intravenous ergot preparations are easily available and do not have the undesirable effects noted with pituitrin

Summary

Satisfactory analgesia and anesthesia can be provided in obstetrics by inhalation methods with safety for mother and baby The agent and technic best suited to the obstetric procedure and the obstetrician should be used

Procedure at the Deaconess Hospital has been described and the statistics for 1948 presented

"DOCTOR JONES" SAYS—

The scientific studies they've been making of alcoholism here of late—why some people can drink in moderation and some others, the "alcoholics," can't take a drink without drinking to excess—it's interesting to consider how completely they've changed our conceptions of the causes of alcoholism When I was young the old idea still prevailed, pretty generally, that it was a matter of weak will power, moral delinquency, or just plain cussedness Today, as a result of the research and so on, practically all physicians believe it's a disease that's at the bottom of it

Most of the forty or fifty thousand members of Alcoholics Anonymous have accepted that view Of course some of 'em—it comes kind of hard to admit they're suffering from a "disease" They could call it a sickness, disorder, complex, it might sound better but it'd amount to the same thing

What kind of a disease it is well, we'll know more about that as the studies progress I suspect a majority of 'em, it's a psychoneurosis emotional conflicts based on repressed childhood memories They affect different people different ways fears of crowds, closed places, women, invalidism, stomach ulcers, compulsive tremors, compulsive drinking—I've seen all those just among my personal friends

Some alcoholics, possibly the majority, it could be lack of some internal secretion or vitamin—like in diabetes, pernicious anemia, night blindness, and the alcoholic neuritis we used to see commonly Heredity may figure in some cases Some—it could be mainly habit, like narcotic addiction, but it probably goes deeper'n that

They'll eventually find out the causes of alcoholism, then they should know better how to prevent and cure it

In the meantime, Alcoholics Anonymous, with its 'group therapy,' is keeping thousands of potential alcoholics on the Water Wagon The Water Wagon, by the way, didn't go out with the horse and buggy It's been motorized and completely modernized and is an increasingly commodious, respectable, and safe conveyance It offers special inducements to young people—*Paul M Brooks, M D*

small amounts of ether are usually added or a change made to cyclopropane if adequate oxygenation is to be maintained

Ethylene may also be used to provide analgesia, but it is only slightly more potent than nitrous oxide, much less pleasant to inhale, and inflammable, thereby providing an added hazard in its use

Cyclopropane is a potent inflammable gas capable of providing surgical anesthesia with adequate oxygenation Its potency and inflammability make it less useful for analgesia because of the danger of explosion with intermittent application and the ease of slipping into surgical anesthesia with resulting diminution of uterine contractions Cyclopropane is the only inhalation agent with which it is possible to preserve normal fetal respiration and still provide surgical anesthesia for the mother Delivery under cyclopropane anesthesia should be completed within fifteen minutes in order to minimize the possibility of fetal asphyxia, since it is estimated that in fifteen minutes the concentration in both fetal and maternal blood streams will be the same The favorable action of cyclopropane in the presence of shock and hemorrhage has been shown by Hershey and Rovenstine [3] In cardiac disease its smooth, quick induction reduces strain on the heart When irregularities are present, it is well to add small amounts of ether In cesarean sections cyclopropane is the preferred inhalation agent The addition of small amounts of ether or curare will provide additional relaxation whenever necessary The increased proportion of oxygenation possible during cyclopropane anesthesia is of added value in all instances

General Management

It does seem that the instruction of expectant mothers as to what happens and as to what they should do in the normal physiologic process of having a baby is too often neglected As a result, they are fearful, may not cooperate too well, and sometimes eat too much after labor has started, thereby often prolonging labor and endangering their own health as well as their baby's The perception of pain varies tremendously in different patients They should be reassured and relief of pain provided by the judicious use of drugs so that the maximum comfort consistent with minimum effect on uterine contractions and fetal respiration will be provided Such drugs as Demerol, the barbiturates, scopolamine, paraldehyde, and opiates are used to provide analgesia, amnesia, and comfort during labor Morphine is usually not given within four hours of anticipated delivery

As the second stage continues and if the ordinary analgesic drugs are not providing sufficient relief, nitrous oxide, intermittently or continuously administered, will provide safe analgesia The patient should be instructed to bear down with the uterine contractions and so assist the uterus in its work With deeper anesthesia necessary for the expulsion or extraction of the baby, small amounts of ether are added, or cyclopropane is used if sufficient oxygenation is to be maintained Following delivery of the baby and while the cord is still pulsating, flushing the patient with oxygen will minimize any asphyxia should it be evident in the baby

Whenever resuscitation of the newborn is required, it should be done promptly, and artificial respiration applied immediately following aspiration of mucus, blood, or other secretions from the mouth and pharynx Oxygen may be administered by means of a mask and bag, infant resuscitator, or by a catheter in the trachea

The aspiration of vomitus is an ever-present danger in obstetric anesthesia, and it is well to consider each patient as having a full stomach unless proved otherwise Only through constant alertness, the immediate application of suction and gravity drainage, and the manual removal of food particles when necessary can this hazard be minimized

Procedure at the Deaconess Hospital

During 1948, there were 1,622 anesthetics given to obstetric patients at the Deaconess Hospital Of these, 1,592, or 98 4 per cent, were inhalation, and 28, or 1 6 per cent, were spinal There was one death due to aspiration Newborn deaths were 1 7 per cent and stillborn deaths 2 4 per cent Cesarean sections numbered 51, or 3 1 per cent, of the obstetric cases

At present Demerol is the favorite premedicant and analgesic in use at the hospital It is felt that this drug provides the greatest relief to the mother with the least disturbance to the progress of labor and to the baby The other drugs that are generally used, such as the barbiturates, scopolamine, and morphine, are only used to a limited extent

When the patients are ready for delivery, they are taken into the delivery room and cyclopropane administered by the carbon dioxide absorption technic Light surgical anesthesia is used and delivery usually accomplished with low forceps with or without episiotomy Added oxygen is administered immediately after the delivery while the cord is still pulsating In more difficult forcep deliveries small amounts of ether are added to the cyclopropane whenever additional relaxation is necessary

Cyclopropane was used in 1,360, or 83 8 per cent, of the obstetric deliveries Chloroform was used in 213 cases, or 13 1 per cent, of the

obstetric anesthetics It was used particularly in those deliveries requiring extreme relaxation of the uterus such as podalic version and extraction or where birth was imminent and anesthesia started in bed or on the cart The amount of chloroform used is generally less than one ounce, and it is administered with the open technic, a Yankauer mask being used and held at least one finger breadth away from the face The eyes are protected with a folded towel The patient's pulse, color, respiration, and eye signs must be watched carefully Although we are mindful of its toxic effects, this agent has been safe and dependable in our hands In a survey of maternal mortality from 1941 to 1945 in Erie County by the Maternal Mortality Committee of the Buffalo Obstetrical Council, it was estimated that in over 50,000 chloroform anesthetics there had been only three deaths

The aspiration of vomitus is an ever-present danger in obstetric anesthesia, and it is well to consider each patient as having a full stomach unless proved otherwise Only through constant alertness, the immediate application of suction and gravity drainage, and the manual removal of food particles when necessary can this hazard be minimized

Procedure at the Deaconess Hospital

During 1948, there were 1,622 anesthetics given to obstetric patients at the Deaconess Hospital Of these, 1,592, or 98 4 per cent, were inhalation, and 28, or 1 6 per cent, were spinal There was one death due to aspiration Newborn deaths were 1 7 per cent and stillborn deaths 2 4 per cent Cesarean sections numbered 51, or 3 1 per cent, of the obstetric cases

At present Demerol is the favorite premedicant and analgesic in use at the hospital It is felt that this drug provides the greatest relief to the mother with the least disturbance to the progress of labor and to the baby The other drugs that are generally used, such as the barbiturates, scopolamine, and morphine, are only used to a limited extent

When the patients are ready for delivery, they are taken into the delivery room and cyclopropane administered by the carbon dioxide absorption technic Light surgical anesthesia is used and delivery usually accomplished with low forceps with or without episiotomy Added oxygen is administered immediately after the delivery while the cord is still pulsating In more difficult forcep deliveries small amounts of ether are added to the cyclopropane whenever additional relaxation is necessary

Cyclopropane was used in 1,360, or 83 8 per cent, of the obstetric deliveries Chloroform was used in 213 cases, or 13 1 per cent, of the

main in the hands of properly trained and supervised anesthetists, because the only serious hazards of these methods reside in errors of anesthetic management Experienced and skillful administration is far better than giving antidotes

On the other hand, however, it is the obligation of the anesthetist to acquire that obstetric knowledge that is so essential for the properly timed beginning of caudal or spinal analgesia in labor, for the intelligent observation of the course of labor, and for the altered physiology of the patient From my own experience I know that anesthesiologists can readily be educated to serve in these ways I regret the tendency in many hospitals for caudal or "saddle block" analgesia to be controlled by obstetricians, because I am aware that most accidents with these technics have occurred in the hands of those unskilled in the prevention and treatment of anesthetic hazards But I hold the anesthesiologists to be partly responsible for this lamentable situation In these cases they failed to supply the demand with a trained and reliable service available to all members of the department of obstetrics at all times

At every delivery the obstetrician should have present some one with an adequate knowledge of fetal respiration and experience and skill in the technics of newborn resuscitation, including endotracheal intubation when necessary The department of anesthesiology must train or supply such expert personnel The specific person in the team may be a resident obstetrician or pediatrician. In my own practice, however, I regularly have an anesthesiologist present

Cesarean sections, especially of the extraperitoneal types, are best performed under spinal anesthesia Realizing that this is the method most easily applied incorrectly, I insist that it be administered only by an expert Spinal anesthesia owes its spotty reputation to the ease with which it can be abused by the uninformed or the inattentive anesthetist Tragic consequences can result from the omission of the safeguards of the technic or from the commission of anesthetic errors Spinal anesthesia is not a routine method, however With a completely competent and cooperative anesthetic service, I know that, if the patient is not suitable for a single dose method, she may receive a fractional spinal or continuous caudal technic or cyclopropane or pentothal and curare I might even be advised to use local anesthesia In any case I know that the patient is individualized for the choice of anesthetic technic Furthermore, the anesthesiologist considers his duties to include not only the administration of analgesia and oxygen but also the restorative fluid and drug therapy as indicated by the changing medical status of the mother In addition, he assumes the care of the newborn so that the airway is cleared immediately, good oxygenation is secured promptly, and optimum pulmonary ventilation is stimulated without delay The anesthesiologist at a cesarean section, even more than at a normal delivery, should be expected to diagnose and prescribe for the continued maintenance of adequate respiration and circulation until the newborn is under the care of the nursery pediatrician The anesthesiologist's extensive experience with subnormal states of respiration and circulation should be applied more often to the safeguarding of the newborn's critical first twenty-four hour period

The obstetrician is aware that hemorrhage is the greatest single cause of maternal death today It is, therefore, a great measure of comfort to the obstetrician and safety to the patient to have an anesthesiologist present who can be depended upon to infuse blood or plasma or stimulants immediately and in adequate amounts, regardless of the state of the veins and the circulation Even if it requires the sternal route and high pressure methods, the obstetrician is confident that the anesthesiologist can overcome hemorrhagic shock which develops more frequently and more rapidly in obstetrics than in general surgery

The obstetrician should have the interested and informed cooperation of the anesthesiologist so that he may avoid the many occasions for hazardous synergistic combinations which exist between obstetric drugs and anesthetic agents, e g , pituitrin and cyclopropane or pentothal, epinephrine and cyclopropane or chloroform, pituitrin and ephedrine Such service can be furnished only by anesthetists who are as interested in obstetric practice as they always are in surgical procedures

The anesthesiologist should be prepared to advise and evaluate the many and varied regimes of sedatives, narcotics, and amnesics recommended for first-stage relief of pain The optimum use of morphine, apomorphine, scopolamine, meperidine (Demerol), paraldehyde, barbiturates, and ether-in-oil requires thorough knowledge of their pharmacologic and clinical properties Any one or a combination of these drugs may be more suitable for a given patient It is the unique opportunity of the obstetrically minded anesthetist to be able to advise the many members of an obstetric service of the particular applicability of one or other of these depressants, which are the special interest of the anesthetist Apropos of this, I call attention to the valuable cooperation of the department of anesthesiology in the control of eclampsia by the use of ultra-short-acting barbiturates, curare, and continuous caudal anesthesia

THE OBSTETRICIAN'S VIEW OF MODERN ANESTHESIOLOGY

SAMUEL L SIEGLER, M D , F A C S , Brooklyn, New York

(From the Obstetrical and Gynecological Services of the Unity and Brooklyn Women's Hospitals)

IF ONE were asked, "What are the most important contributions to obstetrics in the past decade?", one might reply that they are those which have reduced maternal mortality in many communities to an almost irreducible minimum Some of the most important of these are adequate and intelligent prenatal care, availability of blood and of other fluid replacement therapy, introduction of the antibiotics and sulfa drugs, newer methods of cesarean sections, a better understanding of the fundamentals of the mechanism of labor, x-ray pelvimetry, and the proper selection of analgesic and anesthetic agents and the technic for the skillful administration for the relief of pain in childbirth In the obstetrics of the future, the control of the now too high infant mortality, approximating, in the United States, between five and six per cent of the newborn, must be given judicious and comprehensive consideration in the management of labor My role in this symposium is to give the obstetric viewpoint concerning obstetric anesthesia and analgesia—in essence, what does the obstetrician expect from modern anesthesiology to assist him in extending the margins of safety in the management of labor, thereby further reducing the morbidity and mortality of mothers and infants?

The significance of the introduction of a new factor influencing the outcome of labor, such as an analgesic or anesthetic drug, extends far beyond the relief of pain, and its consequences may be definitely measurable in terms of life, morbidity, and mortality of both mother and infant The rational practice and principles of the pharmacologic and clinical evaluation of these drugs, their successes or failures in obstetrics, is now the problem of the anesthesiologist, who should also be part of the obstetric team in any well-regulated obstetric clinic or hospital The knowledge, skill, judgment, and cooperation of the obstetrician, the anesthesiologist, and their associates are the first order of importance in determining the success of any type of analgesia-anesthesia in obstetrics Best results are obtained by adhering rigidly to the warnings, the contraindications, and the "don'ts" of any technic Enthusiasm for any method must be tempered by sound thinking, individualization, and judgment

It is my opinion that the public as a whole is not receiving the best service that modern anesthesiology is capable of supplying It has long been the custom to assign the least experienced anesthetist and the oldest anesthetic apparatus to the delivery room Many of the best hospitals in the country still provide their parturients with a quality of anesthetic service which would never be tolerated in their operating rooms Only because babies are born so commonly and not according to any schedule, even without anesthesia, has this deplorable situation been permitted to develop At least in hospital deliveries there is no longer any excuse for the continuation of this practice The obstetrician should demand that the department of anesthesiology be organized and directed along the lines approved by the American College of Surgeons and the American Hospital Association. The chief of the department should be a physician especially interested in anesthesiology, preferably a diplomate of the American Board of Anesthesiology or a fellow of the American College of Anesthesiologists, if the community can attract or develop one The department should be required to provide or supervise the analgesic and anesthetic requirements of the delivery rooms at all hours, just as it does for the operating rooms It is ironic to note that most anesthesiologists, especially if they are successfully established, refuse to become interested in the quality of anesthetic care in the delivery rooms of their own hospitals It is equally odd to observe an obstetrician accepting the barest minimum of anesthetic service at the hands of the most uninformed and the least useful person in the delivery room, whereas the same man, when acting as a gynecologist, is satisfied only with the services of an expert anesthetist

The obstetric service shqld be able to secure expert administration of any type of analgesia-anesthesia, especially caudal or spinal analgesia, for labor and delivery any time it is desired If the department of anesthesiology cannot offer these technics as a regular service, it is inevitable that they are unavailable when most needed for parturients complicated by heart failure, toxemia, hypertension, and in respiratory and metabolic cases, as well as in those abnormal conditions that might interfere with the lifeline of the fetus, as in premature separation of a placenta, eclampsia, dystocia, prolonged labor, etc It is the duty of the obstetrician to insist that these technics re-

Presented at the 143rd Annual Meeting of the Medical Society of the State of New York Buffalo Section on Anesthesiology May 4 1949.

REPORT OF CLINICAL ANESTHESIA IN GYNECOLOGIC SURGERY

GEORGE H FINER, M D , SARAH JOFFE, M D , and S G HERSHEY, M D , New York City

(From the Department of Anesthesia, Beth Israel Hospital)

IT IS A commonly held impression that vaginal and perineal surgery is frequently accompanied by circulatory changes apparently related to the course of anesthesia For instance, at this hospital it has been noted consistently that more patients showed hypotensive episodes during and immediately following these procedures than was observed in other types of major surgery The etiology of these periods of hypotension is not well understood, although several suggestive factors have been measured Case and Stiles reported that the lithotomy position resulted in a greater reduction of vital capacity than any other commonly used operative posture [1] In addition, these operations involve a slow, continued blood loss not easy to estimate visually Omission of intravenous supportive therapy has been labeled one cause, and, inevitably, various anesthetic agents have been implicated It would seem worthwhile, therefore, to attempt to find any constant factors which might operate to produce these depressions of blood pressure

Hypotensive episodes were associated with three different clinical pictures Those patients whose pressure dropped at the beginning of surgery had almost all had spinal analgesia with a comparatively high sensory level This clinical picture is too familiar to dwell on here The patients were all treated satisfactorily with vasopressors and, in some cases, oxygen and suffered no ill-effects except for nausea and retching This type is not the primary interest of this report

A more significant type of circulatory depression occurred during operation In most cases these patients presented the clinical phenomena usually associated with traumatic or hemorrhagic shock. Pulse rate varied, depending on the anesthetic technic, but pulse pressure was always low The skin was cold, pale, and often moist, and conscious patients were usually restless and nauseated These patients were treated by administration of parenteral fluids, blood being the major agent ordinarily In most instances the hypotension was corrected without undue difficulty unless there had been frank hemorrhage In these latter cases adequate blood replacement was necessary before the blood pressure showed improvement (Figs 1 and 2)

The hypotension seen at the end of operation was of quite a different order Here it occurred suddenly, immediately after anesthesia was discontinued In some, anesthesia was deliberately stopped early (while the lithotomy position was still maintained) in order to see whether posture was a factor Regardless of position, this type of circulatory depression came on when the concentration of anesthetic agent was sharply reduced, as observed by Waters [2] A number of these patients presented the same picture as that described previously, but most showed no evidence of disturbance except for the hypotension The pulse was slow with good pulse pressure If conscious, the patients appeared comfortable The skin was warm and dry although pale This is in agreement with the discussion of "cyclopropane shock" by Dripps and many earlier authors [3] Correction of this condition proved relatively simple If there had been no undue blood loss, those patients who had no treatment beyond keeping them quiet had a return to normal blood pressure levels within fifteen minutes If a vasopressor was injected intravenously, as it was in others of this group, the blood pressure immediately rose to normal levels and remained there If the patient had suffered more than average blood loss, the administration of a vasopressor would, in almost all cases, cause a return to normal blood pressure levels with a concomitant rise in pulse rate, but in many cases this was only transitory In all these patients the administration of blood resulted in a rapid return to preoperative levels, even when only a small fraction of the previously lost blood had been replaced This improvement was maintained The general impression is that this terminal hypotension is of relatively little importance and can be treated with no difficulty and with certainty of response (Fig 3)

Analysis of Cases

The anesthesia and operative records of all patients undergoing major vaginal surgery in the Beth Israel Hospital during the past three years were analyzed This included 800 consecutive cases This short period of time was taken so that certain factors could be kept more constant For example, the surgery for private patients was done almost entirely by the same small group of gynecologists, the residents, although changing performed their surgery under the supervision of

Presented at the 143rd Annual Meeting of the Medical Society of the State of New York, Buffalo Section on Anesthesiology May 4 1949

The obstetrician is easily satisfied with a very light level of inhalation anesthesia for the terminal phases of a normal delivery However, for internal versions or in the presence of complicating factors in the mother, e g, asthma, bronchitis, toxemia, heart disease, the problem of general anesthesia for vaginal delivery becomes as serious as for major surgery Aspiration phenomena tend to occur quite commonly in obstetric anesthesia Respiratory obstruction is a real hazard in the excited, unpremedicated parturient handicapped by a full-term pregnancy and the common tendency to obesity It is incumbent on the anesthetist to recognize these dangers and choose technics appropriate for the circumstances

A preventable anesthetic death or serious complication is always deplorable, but it is most tragic and lamentable when it occurs in obstetrics The abrupt substitution of an unexpected calamity for a long-awaited happy event shocks every member of the family and the hospital staff The obstetrician, dealing with risk in the lives of two patients, has a grave responsibility He should demand and obtain the services and cooperation of a real department of anesthesiology The teamwork which contains the best of modern anesthesiology is a necessity if we are to reduce further the maternal and fetal mortality and morbidity rates

As has been said of public health, good obstetric anesthesia is a purchasable commodity I have obtained it and brought the anesthesiologist to stay in the labor and delivery rooms by the invariable use of his services on an individual fee basis for which the patients are responsible The patients are aware of what they are getting and for what they are paying In 750 consecutive caudal and "saddle block" analgesias and in 136 consecutive cesarean operations, I have had no maternal mortality and a fetal mortality, both stillborn and neonatal, of 2 9 per cent

In most instances, the modern American woman demands some relief from the pain of childbirth, and this is quite understandable It is, therefore, the duty of all of us who are interested in this specialty to afford her this relief if it can be given without jeopardizing herself and her unborn child A newer knowledge has been created in obstetric analgesia and anesthesia, one that cannot be learned overnight The methods discussed here are not for the casual user and are for the most part hospital procedures There is no single form of pain relief best suited for every case

Conclusions

1 Individualization of the patient should be the inflexible rule in the administration of analgesia-anesthesia in obstetrics

2 Teamwork and cooperation between the anesthesiologist and obstetrician are the prerequisites for the well-being and comfort of mother and baby

3 A well-staffed maternity hospital should have trained personnel available who have the ability to administer expertly, efficiently, and skillfully any of the many anesthetic methods deemed necessary

4 In the obstetrics of the future such cooperation will prevent transplacental narcotization of the fetus, thus avoiding the risk of asphyxia neonatorum, and the mother will be spared much of the anguish, fear, and tension of pain in childbirth, thereby further reducing maternal mortality and morbidity

CONTROL OF TUBERCULOSIS

Despite a falling death rate, tuberculosis is now "out of control" in New York City This statement was made by Drolet, statistician for the New York Tuberculosis and Health Association Department of Health figures for the first three months of 1949 show a 26 per cent increase in the number of new cases of the disease reported in the city over the same three months of 1948, a year in which 8,551 new cases were listed There were 2,476 new cases reported this year up to April 1, as against 1,959 for the first three months of last year On April 1, 1949, there were 19,284 known cases of the disease in the city

For the first quarter of this year, there were 866 deaths from tuberculosis recorded in the city, a drop of 658 from the same period of last year, or 24 per cent "The lower mortality may well represent more successful treatment of tuberculosis, particularly by newer surgical procedures and by the use of newer antibiotic drugs, such as streptomycin," Mr Drolet said "On the other hand, the conclusion is inescapable that the attack rate is much greater now than it was just one year ago We cannot overlook the probability that inadequate hospital facilities, plus the inadequacy of other means of isolation of infectious cases, may be in great part responsible for the situation being, for the time at least, out of control"—*May 18, 1949*

REPORT OF CLINICAL ANESTHESIA IN GYNECOLOGIC SURGERY

GEORGE H FINER, M D , SARAH JOFFE, M D , and S G HERSHEY, M D , New York City

(From the Department of Anesthesia, Beth Israel Hospital)

IT IS A commonly held impression that vaginal and perineal surgery is frequently accompanied by circulatory changes apparently related to the course of anesthesia For instance, at this hospital it has been noted consistently that more patients showed hypotensive episodes during and immediately following these procedures than was observed in other types of major surgery The etiology of these periods of hypotension is not well understood, although several suggestive factors have been measured Case and Stiles reported that the lithotomy position resulted in a greater reduction of vital capacity than any other commonly used operative posture [1] In addition, these operations involve a slow, continued blood loss not easy to estimate visually Omission of intravenous supportive therapy has been labeled one cause, and, inevitably, various anesthetic agents have been implicated It would seem worthwhile, therefore, to attempt to find any constant factors which might operate to produce these depressions of blood pressure

Hypotensive episodes were associated with three different clinical pictures Those patients whose pressure dropped at the beginning of surgery had almost all had spinal analgesia with a comparatively high sensory level This clinical picture is too familiar to dwell on here The patients were all treated satisfactorily with vasopressors and, in some cases, oxygen and suffered no ill-effects except for nausea and retching This type is not the primary interest of this report

A more significant type of circulatory depression occurred during operation In most cases these patients presented the clinical phenomena usually associated with traumatic or hemorrhagic shock Pulse rate varied, depending on the anesthetic technic, but pulse pressure was always low The skin was cold, pale, and often moist, and conscious patients were usually restless and nauseated These patients were treated by administration of parenteral fluids, blood being the major agent ordinarily In most instances the hypotension was corrected without undue difficulty unless there had been frank hemorrhage In these latter cases adequate blood replacement was necessary before the blood pressure showed improvement (Figs 1 and 2)

The hypotension seen at the end of operation was of quite a different order Here it occurred suddenly, immediately after anesthesia was discontinued In some, anesthesia was deliberately stopped early (while the lithotomy position was still maintained) in order to see whether posture was a factor Regardless of position, this type of circulatory depression came on when the concentration of anesthetic agent was sharply reduced, as observed by Waters [2] A number of these patients presented the same picture as that described previously, but most showed no evidence of disturbance except for the hypotension The pulse was slow with good pulse pressure If conscious, the patients appeared comfortable The skin was warm and dry although pale This is in agreement with the discussion of "cyclopropane shock" by Dripps and many earlier authors [3] Correction of this condition proved relatively simple If there had been no undue blood loss, those patients who had no treatment beyond keeping them quiet had a return to normal blood pressure levels within fifteen minutes If a vasopressor was injected intravenously, as it was in others of this group, the blood pressure immediately rose to normal levels and remained there If the patient had suffered more than average blood loss, the administration of a vasopressor would, in almost all cases, cause a return to normal blood pressure levels with a concomitant rise in pulse rate, but in many cases this was only transitory In all these patients the administration of blood resulted in a rapid return to preoperative levels, even when only a small fraction of the previously lost blood had been replaced This improvement was maintained The general impression is that this terminal hypotension is of relatively little importance and can be treated with no difficulty and with certainty of response (Fig 3)

Analysis of Cases

The anesthesia and operative records of all patients undergoing major vaginal surgery in the Beth Israel Hospital during the past three years were analyzed This included 800 consecutive cases This short period of time was taken so that certain factors could be kept more constant For example, the surgery for private patients was done almost entirely by the same small group of gynecologists, the residents, although changing, performed their surgery under the supervision of

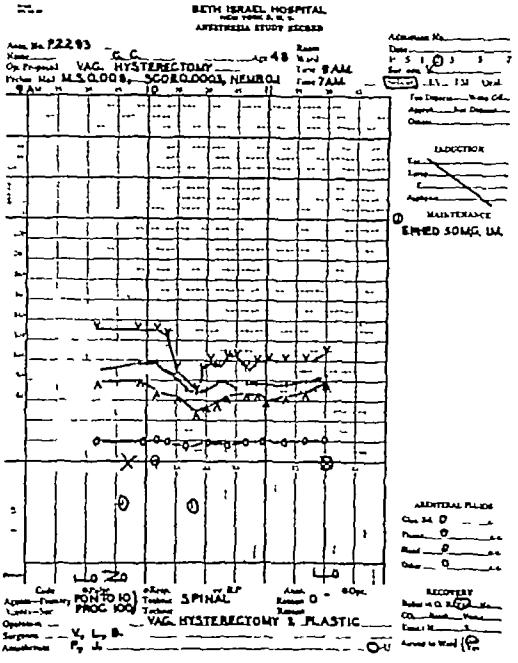

FIG 1 Type of hypotension occurring during spinal analgesia

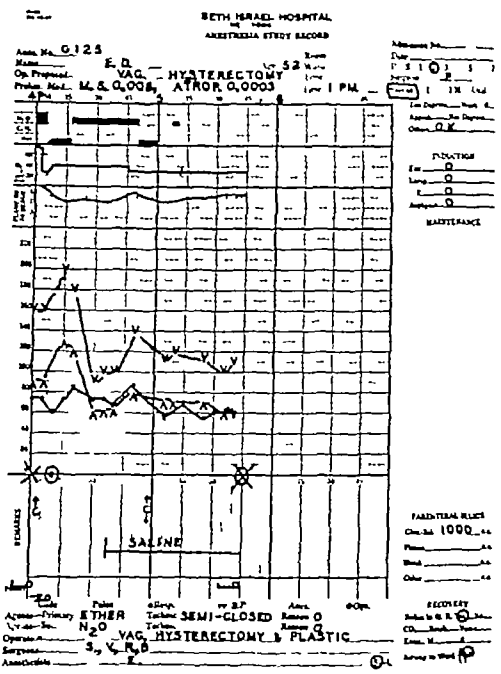

FIG 2 Type of hypotension occurring during ether administration

the same staff gynecologists A similar situation applied to the anesthetists The operative procedures, quite standardized in this hospital, were not significantly altered in this period Two changes that did occur were the more frequent use of intravenous supportive therapy and a shift from spinal to inhalation anesthesia as the method of choice For the past two years the trend has been to use cyclopropane more frequently and almost always in cases in which the patient was a poor risk or where excessive hemorrhage might be anticipated

Of 800 cases, 235 (29 per cent) showed a significant fall in blood pressure during or immediately after operation (A significant fall was recorded if the mean pressure dropped 20 per cent below the initial reading or if a smaller fall in pressure was accompanied by a low pulse pressure or other signs of disturbed circulation) There were 31 patients showing hypotension within five minutes of induction of anesthesia, 26 of these had received spinal analgesia with sensory levels above the sixth thoracic nerve This is a not uncommon effect Of the others, four were patients who were markedly apprehensive and had initial blood pressures above their usual levels The remaining patient received a relative overdose of anesthetic agent during the induction. As stated before, this type of hypotension is of secondary interest here.

Of more pertinent interest were 123 patients who developed hypotension during the operation and 81 more whose blood pressure fell when anesthesia was discontinued At first an attempt was made to correlate pulse rate changes with the patient's condition, but it was found that of the 235 cases only 20 showed a pulse rate increase of more than 20 per minute, even when the blood pressure fell to very low levels Almost all of these 20 patients had relatively large blood losses It seemed from this that pulse rate by itself is not a reliable index of the state of the circulation in these circumstances

The patients were then grouped in other ways in order to uncover the variables which might be correlated with hypotension

Age.—The scarcely surprising conclusion from the figures shown is that patients under forty withstand major surgery better than those over forty (Table 1)

Physical Status.—Patients were grouped according to the standards of the American Society

TABLE I.—CORRELATION OF AGE WITH HYPOTENSIVE EPISODES

Age	Number of Patients	Per Cent Showing Hypotension
20 to 30	27	15
30 to 40	165	21
40 to 50	306	32
50 to 60	201	32
60 to 70	89	32
70 to 80	11	27

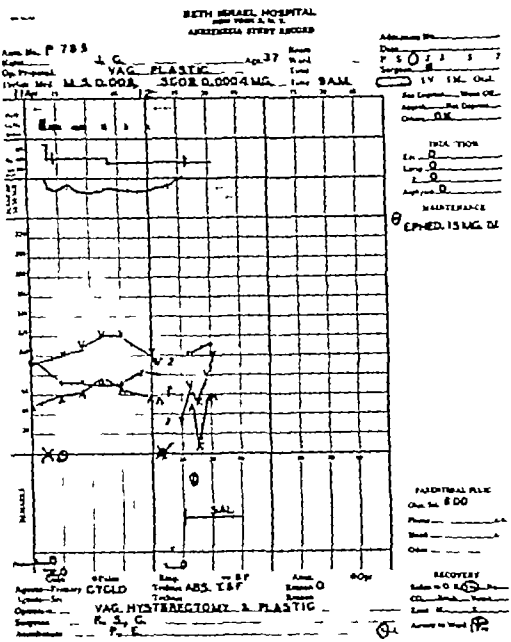

FIG 3 Type of hypotension occurring at end of cyclopropane administration

of Anesthesiologists in which groups I, II, and III correspond to good, fair, and poor risks These results were similar to those found in other types of surgery (Table 2)

Operating Time —These figures would indicate that operating time was not an important consideration, although the cases lasting less than one hour showed up to slight advantage (Table 3)

Surgeons —As was expected, cases done by the staff gynecologists had hypertension in 26 per cent, while cases done by residents under supervision of the same surgeons showed hypotension in 34 per cent

Parenteral Therapy —In the period covered by this study there was a change in supportive therapy Until 1947, parenteral fluids were given

TABLE 2 —RELATION OF PHYSICAL STATUS TO HYPOTENSIVE EPISODES

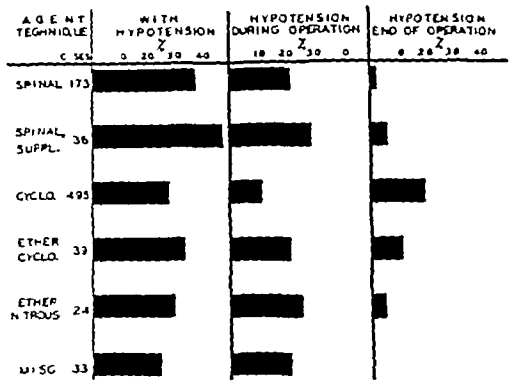

FIG 4 Frequency and time of hypotension correlated with agent

during operation only if it was deemed necessary because of a change in the patient's condition During part of 1947 and all of 1948, most patients came to the operating room with infusions For the most part these were of saline solution. In 1946, for example, there were 222 cases of major vaginal surgery, and only 86 of these patients received parenteral fluids Hypotension occurred in 30 per cent of the cases In 1948, on the other hand, of the 220 cases 183 had infusions, yet, hypotension was seen in 31 per cent Thus, the use of an electrolyte solution, of itself, did not seem to stabilize the circulation It was our impression that blood given throughout the operation was of much greater benefit, but because of the possibility of side-reactions and the presence of economic obstacles it was impractical to use blood prophylactically, except in those patients who presented severe anemia at the time of operation

The outstanding difference was noted in the frequency and time of onset of hypotension as correlated with the various anesthetic agents From Fig 4 it can be seen that more patients developed hypotension during spinal anesthesia (especially when supplemented by another agent) than with inhalation agents Characteristically, hypotension during spinal and ether anesthesia occurred during the operation, while hypotension with cyclopropane was seen most often at the end of operation, the so-called "cyclopropane shock." When cyclopropane and ether were both used, the effects of each seemed combined, but the addition of cyclopropane appeared to delay the hypotension as long as the drug was present

There were very few major postoperative complications in the series No deaths occurred Of 800 cases, 22 developed major complications Of these, only eight showed blood pressure falls at the

time of operation Complications included thrombophlebitis in three patients, with pulmonary embolus following in two of them Three patients developed pneumonia, and one had a coronary occlusion postoperatively There were three cases of severe distention and two with unduly protracted urinary retention Two patients developed neuroses, and eight had severe prolonged headaches following spinal anesthesia All agents were involved, and in this small number of complications no correlations could be made for the headaches

Comment

The development of the anesthetic management in this group of cases is of some interest With the change to the use of cyclopropane as the inhalation agent in the majority of patients, it was observed that hypotension at the close of operation occurred more frequently This seemed to be the most important factor since age, physical status, and duration of operation, although significant, did not account for the high incidence of hypotension Furthermore, the routine administration of glucose and saline infusions did not seem to be efficient prophylactically It was decided, therefore, that ether should be used as the primary agent in major vaginal procedures in order to see if this phenomenon could be avoided

However, as shown in this analysis, hypotension occurred even more frequently with ether anesthesia or with spinal analgesia, but it took place during the operation and was accompanied by signs of circulatory distress in the patient Cyclopropane, on the other hand, appeared to delay the onset of hypotension and convert it to a relatively benign state but did not minimize its frequency Hershey *et al* have shown that normal compensatory reactions to hemorrhage, as measured in the peripheral circulation, are depressed less by cyclopropane than by ether [4] Spinal analgesia, too, by blocking sympathetic pathways, retards compensatory responses These clinical results seem to agree with this interpretation, in that circulatory depression seldom occurred while cyclopropane was being administered, and, if depression did occur when cyclopropane concentration was lowered, it was ordinarily not accompanied by other signs of shock. In fact, this condition may often be undetected if blood pressure is not checked at the conclusion of the operation

Finally, the response to treatment was rapid and uniformly good We feel that, considering the total effect on the patient, cyclopropane produced less derangement of protective mechanisms than the other agents or technics

Summary and Conclusions

The hypertension often seen during or immediately following vaginal surgery was not correlated with postoperative complications

Blood pressure falls were seen more often in patients over forty, in poor risk patients, and in operations more than one hour in duration.

There was more hypotension when spinal analgesia was used, especially if supplemented by other agents, and this occurred during the operation Patients receiving ether reacted in much the same manner

With cyclopropane fewer developed hypotension during operation although more was seen at the conclusion of cyclopropane administration However, this condition was easily treated by vasopressors, blood, or rest in bed and was seldom accompanied by other signs of shock

Discussion

Lester C Mark, M D , *New York City* (*By invitation*) —This has been a searching inquiry into the etiology of hypotension associated with gynecologic surgery As has been indicated, the fall in blood pressure encountered with spinal anesthesia has been well-documented and needs no further comment The mechanism responsible for the hypotension which may be seen with general anesthesia is less clearly understood The authors have suggested, as contributing factors, the decrease in vital capacity produced by the lithotomy position and the continued, almost unnoticed, blood loss which may occur during these operations It is very possible that the manipulations involved, such as the exertion of pressure with retractors on the vaginal walls and of traction in the cervix, may stimulate vasodepressor reflexes analogous to those usually associated with surgical procedures within the abdomen It was mentioned here that, unless gross hemorrhage had occurred, the pulse rate rarely increased during the hypotensive episodes but usually decreased or remained unchanged This is evidence in favor of a reflex mechanism Burstein reports good results with curare in the treatment of traction and other reflexes, it would be of interest to investigate its use in these cases

The difference in time relations of the hypotension observed with cyclopropane and with ether is of interest We would anticipate a lag in the appearance of an adverse circulatory reaction with cyclopropane because of the lesser depressant effect exerted by this agent on the homeostatic mechanisms concerned The finding that the incidence of hypotension is distinctly less with cyclopropane than with ether suggests that the concept of "cyclopropane shock" does not apply here It seems more likely that the same factors responsible for the blood pressure fall with ether operate also with cyclopropane, but their effects are masked for the duration of the anesthesia by the beneficent action of cyclopropane on the circulation

The delayed onset of hypotension with cyclopropane has been demonstrated by the authors to be in

dependent of postural changes However, in the presence of impaired vasomotor compensatory mechanisms, as with high spinal or deep ether anesthesia, circulatory embarrassment may be directly attributable to the change from the lithotomy to the horizontal position The resultant disparity between the relatively fixed volume of circulating blood and the now increased volume of the functional vascular bed may readily cause a considerable fall in arterial pressure

Finally, it may perhaps be worthwhile to reiterate the dictum that extremes of position on the operating table should be avoided No anesthetized patient should be placed in a position he would find intolerable if awake

CALLS NCHIP "OLD WORLD SCOURGE"

"Adoption of a system of politically controlled medical practice, as recommended by President Truman, would turn back the clock of medical progress in this country fifty years!" So charged Dr Elmer L Henderson, chairman of the Board of Trustees of the A.M A. who added, "The inevitable deterioration in the quality of care which would result from government-herding of patients and doctors into assembly line medical mills would lower the standards of healthy America to those of sick, regimented Europe "

Dr Henderson's statement follows in part

"President Truman's special message, asking enactment of a National Compulsory Health Insurance Program, deserves most careful scrutiny both by Congress and by the American people, whose health would be seriously endangered if this Old World scourge is allowed to spread to our New World

"There is neither hope nor promise of progress in this system of regimented medical care It is the discredited system of decadent nations which are now living off the bounty of the American people —and if adopted here, it would not only jeopardize the health of our people, but would gravely endanger our freedom It is one of the final, irrevocable steps toward State Socialism, and every American should be alerted to the danger

"One of the great dangers in political diagnosis of the health needs of the people is the temptation to over-simplification President Truman has fallen into this error The President sets forth an objective which all of us can warmly endorse—namely, bringing adequate health services within the reach of all the people The doctors of America, in cooperation with the prepaid medical and hospital care plans and the many splendid voluntary health insurance systems, have made great progress in achieving that objective, so we have no quarrel with the President on that score

"President Truman, however, proceeds from a desirable objective to a highly undesirable proposal for achieving that objective There is a great deal of double talk in the President's message, but what he actually proposes is a National Compulsory Health Insurance System which would regiment doctors and patients alike under a vast bureaucracy of political administrators, clerks, bookkeepers, and lay committees

"Every wage-earner, every self-employed person and every employer would be compelled to contribute exorbitant payroll taxes, eventually mounting to a tax of 8 or 10 per cent on every paycheck, to support this system, and the cost of medical care, instead of being reduced, would be doubled and trebled by bureaucratic overhead The record is clear in every country where Compulsory Health Insurance has been adopted It is cheap in quality, but extravagantly high in price

"The President's message, in some respects, was persuasive and disarming The ideals and objectives were stated in glowing terms, but the message was completely lacking in any specific statement of the services to which the people would be entitled, or any estimate of the taxes which they would be compelled to pay

"There are many fallacies and misstatements in the President's message, some of which cannot go unchallenged President Truman, for example, is about a decade behind the times in his statistics on the growth of the Voluntary Health Insurance Systems He falls into the error of stating that only limited, inadequate health protection is available under the Voluntary Health Insurance Systems Actually, the voluntary systems are providing better coverage today than any compulsory program yet proposed—at about half the price.

"The most serious misstatement in the President's message—and one which it is regrettable any President of the United States would have uttered—is the repetition of that now completely discredited statement that tens of thousands of persons die needlessly in this country, due to lack of medical care. The President, in this instance, as in others, undoubtedly based his statement on the distorted report of the Federal Security Administrator, whose listing of 'needless deaths' included 40,000 deaths from accidents and 115,000 from cancer and heart disease It is shocking that any government department head would seek to impose on the credulity of the American people with such flagrant misrepresentations—and it is unfortunate, indeed, that the President of the United States should have repeated even in part, this misinformation

"There is a very real need in America for the budgeting of medical costs, and American medicine is proud of the part it has played in building the Voluntary Health Insurance Systems to meet that need There is no need however, for compelling the American people to join a government system. The voluntary way is the American way—and the people will resolve this problem, in a very short span of years, under the voluntary systems now available to them."

QUANTITATIVE PHARMACOLOGIC STUDIES WITH PENTOTHAL

LESTER C MARK, M D ,* E M PAPPER, M D , BERNARD B BRODIE, Ph D ,* and E A ROVENSTINE, M D , New York City

(From the Department of Anesthesiology, New York University Post-Graduate Medical School, the Department of Biochemistry, New York University College of Medicine, and the Research Service, Third New York University Medical Division, Goldwater Memorial Hospital)

DESPITE the sustained popularity of sodium pentothal, as indicated by the accumulation of voluminous clinical experience with this agent, little information of a fundamental pharmacologic nature has been available The clinical parallel of this gap in pharmacologic understanding is the lack of adequate criteria for establishing the depth of anesthesia with pentothal. A serious and provocative attempt to correct this deficiency was advanced by Etsten and Himwich who correlated clinical signs with descending depression of the neuraxis, starting with the newer phyletic areas of the brain and progressing to the more primitive portions [1] Even these workers admitted that the "observations made both on animal and man reveal that some of the clinical signs are out of proportion to the depth of anesthesia " With the aid of sensitive and specific chemical methods for the identification of pentothal and its metabolites, which were devised and are being reported elsewhere, it became feasible to undertake accurate observation of the drug in vivo [2] The implications of such studies for the anesthesiologist are stressed in this report

Since the plasma is the medium of distribution of pentothal to its sites of action in the body, a systematic inquiry into the behavior of pentothal in man must begin with the factors affecting the plasma concentration of the drug and hence, presumably, the clinical effect These factors are the rate of excretion, the rate of transformation, and the extent of localization in the organs and tissues of the body

Urinary excretion of pentothal after its intravenous administration in large doses (2 to 4 Gm) in man was negligible, indicating that the compound is almost completely metabolized in the body Two transformation products were recovered from the urine These accounted for less than 30 per cent of the parent drug injected, suggesting further metabolism in vivo by an as yet unknown route The ultraviolet absorption characteristics of these transformation products indicate that the ring structure of the barbiturate nucleus is still intact and that the chemical alterations incurred have presumably affected the longer, i e , the methylbutyl, side-chain One of these metabolites isolated from the urine has been purified and tested for anesthetic activity in mice Preliminary observations indicate at most a mild sedative action with intraperitoneal doses equivalent to six times the full anesthetic dose of the parent drug Further studies on these metabolites are in progress

Pentothal has been classified as an ultra-short-acting barbiturate because of the generally accepted belief that it is very rapidly detoxified in the body [3] This concept has been difficult to reconcile with the frequent occurrence of prolonged postoperative somnolence following the sustained administration of pentothal It has been tentatively postulated that unidentifiable but pharmacologically active degradation products remaining in the tissues produce the depression [4]

Experiments were conducted to determine the rate of transformation of pentothal in vivo Unpremedicated human subjects received single quick injections of pentothal sodium intravenously in doses of 0 3 to 0 5 Gm in 2 5 per cent concentration Blood samples were drawn at frequent intervals for analysis All subjects lapsed into unconsciousness after a momentary period of stimulation lasting only several seconds and manifested by a sudden spasmodic movement of the head and upper torso As shown in Fig 1, the concentration of pentothal from an initial peak diminishes rapidly at first and then falls more slowly The swift reduction in plasma level might be misinterpreted as indicating speedy destruction of pentothal If this were true, however, the slope of the curve would continue to drop sharply to zero, instead of changing to the slower fall noted Actually, the initial high concentrations observed are "false" in that the measure pentothal in the plasma which has not yet been distributed to all the body tissues with the possible exception of the brain The early rapid decline thus represents a shift of pentothal from the plasma to the tissues rather than its destruction This phase is manifested clinically in the swift recovery from anesthesia as shown by these subjects following the administration of small doses of pentothal The subsequent more gradual decrease in plasma pentothal, accompanied by persistent hypnotic, although not anesthetic,

* By invitation.

Presented at the 143rd Annual Meeting of the Medical Society of the State of New York, Buffalo Section on Anesthesiology May 4 1949

Supported in part by a grant from Abbott Laboratories Inc.

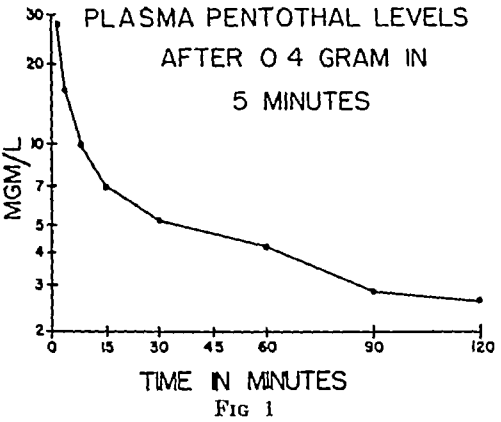

FIG 1

effect, corresponds to the establishment of a state of dynamic equilibrium of drug distribution between plasma water and body tissues Since the renal excretion of pentothal is negligible, the further decline in plasma concentration is due to the process of transformation of the drug The rate of metabolism of pentothal is seen to be slow, about 15 per cent per hour Indeed, appreciable concentrations of pentothal are present in the plasma long after its administration

Metabolites of pentothal are detectable in plasma as early as one hour after the start of intravenous administration These transformation products increase steadily from the equivalent of 4 to 5 per cent of the plasma pentothal concentration after one hour to the equivalent of 35 to 50 per cent twelve to fourteen hours after the administration of larger doses

The concept of plasma-tissue equilibrium merits further comment The exchanges of pentothal between the plasma and the various organ tissues are reversible At any given moment, the plasma level is the resultant of all these local exchanges Equilibrium is achieved when the exchanges are occurring equally in both directions, i e , when the reversible localization of pentothal in the tissues has reached its maximum Only then is the plasma pentothal level a true reflection of the therapeutically active drug concentration The length of time required for the establishment of equilibrium suggests that the tissue localization of pentothal occurs in a gradual manner

The distribution of pentothal in the tissues at equilibrium was studied in the dog Pentothal concentrations in most organ tissues were higher than in plasma, indicating extensive localization of the drug Another significant characteristic of the distribution of pentothal is the degree to which it is bound, presumably by surface adsorption, to the plasma proteins About 80 per cent of the circulating pentothal was found to be so bound Thus the amount of the compound in plasma water (i e , total plasma pentothal less the per cent bound to plasma protein) represents the pharmacologically available drug in the blood stream The disproportion already noted between pentothal in plasma and in the tissue reservoir becomes striking when plasma water pentothal is used as the basis for comparison An interesting observation is that the concentration of pentothal in plasma water is the same as that in cerebrospinal fluid This finding is highly significant, it affords evidence that there is no blood-brain barrier for pentothal in the dog and presumably also in man

The clinical implications of these findings are several The early transient high plasma level may readily result in sudden severe depression of the central nervous system, especially if the absence of a blood-brain barrier for pentothal is confirmed in man The commonly observed phenomenon of early respiratory depression or apnea may be explained on this basis It would also account for the disastrous effects of pentothal when administered incautiously to patients with circulatory depression because of the elimination of central compensatory vasomotor control, as in shock On the other hand, this property may be exploited in healthy patients to facilitate relaxation of the jaw for laryngoscopy and endotracheal intubation The slow rate of transformation demonstrated is contradictory to the general belief that pentothal is rapidly detoxified in the body The postanesthetic somnolence following prolonged pentothal administration is due to the persistence in the plasma of pentothal itself, in appreciable concentrations which are maintained by the extensive tissue reservoir of the drug

An understanding of the factors affecting the plasma pentothal concentrations reveals that efforts to correlate plasma levels and the clinical signs of anesthesia with pentothal will be valid only after achieving the state of dynamic tissue-plasma water equilibrium described above Furthermore, equilibrium should begin at plasma levels sufficiently high to suppress most of the usual manifestations of depth of anesthesia, in order that the time and sequence of their reappearance may be accurately noted To this end, doses of 3 to 4 Gm of pentothal sodium in 2 5 per cent solution were administered by intermittent intravenous injection over a fifty-minute period Artificial respiration with oxygen was instituted by rhythmic manual compression of the breathing bag in the closed to-and-fro carbon dioxide absorption system Oxygen inhalation was continued until spontaneous ventilation was deemed adequate Observations were made of the arterial blood pressure, pulse rate, respiratory rate, pupil size, and the return of the following dur-

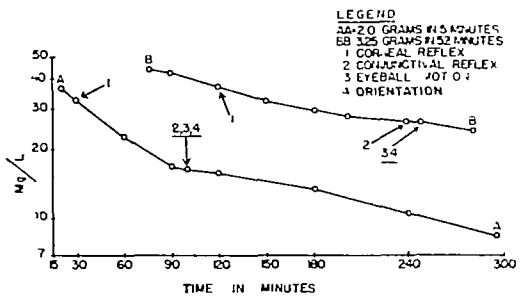

FIG 2 Plasma pentothal levels and the signs of anesthesia after two different dosages [2]

phragmatic breathing, intercostal muscle activity, corneal reflex, conjunctival reflex, pupillary light reflex, eyeball motion, jaw tone, knee jerk, pain response to a standard pinch-stimulus from an Allis forceps applied to the skin in front of the ankle, and orientation, arbitrarily defined as the ability to protrude the tongue on spoken command Repeated trials revealed that, of all the signs listed, the reappearance of the corneal and conjunctival reflexes, eyeball motion, and orientation as described were the most sharply delineated and, hence, especially useful for this study In the same subject receiving equivalent large doses of pentothal at weekly intervals, the plasma pentothal concentrations at which these four signs recurred were approximately reproducible This would indicate that an individual receiving pentothal does not acquire tolerance in the sense of diminished reactivity to the drug administered in similar fashion at a later date

On the other hand, evidence of an acute tolerance to pentothal was found in man When a subject was maintained at high plasma concentrations of the drug, the signs of anesthesia reappeared at higher plasma levels than when he was maintained at low plasma concentrations The duration of narcosis was also increased Figure 2 shows the typical response of the same subject to varied amounts of pentothal administered a week apart The signs reappeared in similar sequence but at significantly different plasma levels Yet the parallelism in slope of the two curves is evidence that the rate of transformation of the compound was unaltered Shideman, Kelly, and Adams observed this phenomenon in the dog under somewhat altered conditions [5] They found that when doses of 10 mg per Kg were repeated at short intervals after apparently complete recovery from narcotic action, the plasma levels at which the righting reflexes returned were successively higher with each additional dose These experiments represent a telescoping in time of our procedure of administrations at weekly intervals, but the findings are analogous Whether the manifestation of acute tolerance to pentothal depends specifically upon the total dose administered, the peak plasma levels attained, or the duration of time under the influence of the drug has not been determined The occurrence of acute tolerance makes it impossible to demonstrate a fixed correlation between plasma pentothal concentrations and the signs of anesthesia A relative and reproducible correlation does exist when the drug is given in comparable dosage and technic to the same subject on different occasions Pentothal thus differs sharply from the inhalant anesthetic agents, such as ether, cyclopropane, and nitrous oxide, with which depth of anesthesia is predictable within narrow limits for any given plasma concentration

The effects of adjuvant drugs commonly employed with pentothal were studied in one subject At weekly intervals, 3 to 4 Gm of pentothal were administered in 2 5 per cent solution over a fifty-minute period, in order to effect equilibrium at high plasma concentrations The inhalation of 50 per cent nitrous oxide and 50 per cent oxygen for one and one-half hours starting early in equilibrium did not alter the usual plasma time-concentration curve of pentothal, nor did it influence appreciably the plasma levels at which the signs of anesthesia reappeared Curare as *d*-tubocurarine hydrochloride in doses of 100 units during high level equilibrium similarly failed to alter either the rate of transformation of pentothal or the plasma levels at which the various signs returned Ten milligrams of morphine sulfate injected intravenously during equilibrium did not disturb the slope of the curve of plasma pentothal levels, even though respiratory depression occurred The signs of anesthesia did appear at lower pentothal concentrations as compared with the control observations Thus morphine does not affect the metabolism of pentothal but does influence its clinical actions to a moderate degree This effect is probably additive in nature

Summary

Quantitative pharmacologic studies with pentothal elicit the following clinically significant conclusions

1 The accepted classification of pentothal as an ultra-short-acting barbiturate on the basis of its presumed rapid detoxification in vivo is erroneous, since pentothal is almost completely metabolized in the body at a surprisingly slow rate

2 Plasma pentothal concentrations bear no fixed relation to the signs of anesthesia

3 An acute tolerance to pentothal occurs in man

4 Morphine, curare, and nitrous oxide do not affect the transformation of pentothal

Discussion

Merel Harmel, M D, *Albany (By invitation)* — Dr Mark and his associates are to be congratulated on the provocative and careful work which they have presented here It is time indeed that basic data concerning the pharmacology of sodium pentothal should be forthcoming, for it is almost fifteen years since this drug was first introduced into anesthesia The voluminous literature on clinical experience is in marked contrast to the paucity of quantitative pharmacologic information

The stumbling block has been the lack of a specific and accurate method for the quantitative determination of pentothal in blood and tissues Obviously, the value of the results which have been presented will depend entirely upon the specificity and accuracy of the technic employed We hope that this method will soon be generally available so that this important work may be confirmed

There are several items which are deserving of comment Indeed, the multitude of findings make it difficult to know where to begin Of great significance is the apparent slow metabolism of pentothal and its persistence in the plasma-water long after its administration As Dr Mark has pointed out, this fact abolishes the necessity of ascribing the prolonged effects of sustained administration to degradation products

At the same time, the idea of a tissue reservoir is presented Of course, this investigation has explored the where and not the how of pentothal metabolism. I am sure the question comes to mind as to what is the mechanism of the pentothal degradation? The latest evidence on this score would appear to implicate the liver In previous studies, pentothal could not be detected either in the plasma or the tissues, shortly after its administration However, Delmonico and then Anderson and Essex observed a cyclic disappearance and reappearance of sodium pentobarbital in the blood [1 2] This phenomenon would appear to be refuted by Dr Mark's experiments with pentothal

If confirmed in man, the demonstration of pentothal in cerebrospinal fluid in quantities equal to that in the plasma water would be most significant Not only would it postulate no blood-brain barrier, but it would give a means of measuring narcotic activity which would not be altered by other tissue contributions Indeed, may it not be that cerebrospinal fluid levels may correlate with signs of depth of anesthesia This finding is in sharp contrast to the work of Kozelka with other barbiturates in which only a tiny fraction of barbiturate could be found in cerebrospinal fluid [3] The presence or absence of a blood-brain barrier could then well be the basis for the increased activity of the ultra-short-acting barbiturates This certainly focuses attention on the sulfur bond Whether or not radioactive pentothal recently made available will elucidate this problem remains to be seen

I should like to know whether representative samples of various brain areas were subjected to analysis in the animal experiments Some work has indicated a selective site of action for the barbiturates in the brain Koppanyi has, however, maintained that all the brain is equally saturated [4] The evidence here presented would, presumably, support Koppanyi's contention

The clinical implications of this study in shock and in the facilitation of endoscopy have been emphasized I should like to inquire what these results mean in terms of deranged electrolyte and water balance associated with changes in the plasma volumes and the hydration of the tissue compartment

It is encouraging to find that laboratory work sustains the clinical impression All of us who have had occasion to use pentothal repeatedly in short intervals on patients have been impressed with the apparent development of tolerance The answer to the occasional prolonged excitement and disorientation, particularly in the aged patient postoperatively, would appear to be explained by the relatively slow metabolism of pentothal

The multitudinous speculations which the data stimulate could go on *ad infinitum* However, it is clear that this work opens up new vistas, both in an examination of pentothal in particular and barbiturate narcosis in general It is hoped that many of the controversial issues can be settled The importance of this type of investigation cannot be overemphasized, for it must be apparent that, as the fundamental knowledge of sodium pentothal increases, so will the safe and intelligent management of patients increase

PHYSICIANS EARN MORE BY WORKING FOR SELVES

Independent physicians net 43 per cent more income than do doctors on salary, according to a nation-wide survey conducted by *Medical Economics*, national business magazine for physicians Average net income received in 1947 by independent practitioners was $11,300, by their salaried colleagues, $7,914, reports the magazine in its May issue "More than half the salaried men have been in practice less than ten years, as against 37 per cent of independent physicians," the survey reveals Ten per cent of all active, private physicians get more than half their income from salaries

PROPHYLACTIC AND THERAPEUTIC INDICATIONS FOR TRACHEOTOMY DURING SURGICAL INTERVENTION

PASCAL FRISCIA, M D , and HAROLD F BISHOP, M D , New York City

(From the Veterans Administration Hospital, Kingsbridge)

THERE are many reports in the medical literature which describe specific surgical problems requiring tracheotomy preliminary to or during surgery to establish and maintain an adequate airway The parallel advances in surgery and anesthesiology during the past score of years have so increased the scope and magnitude of surgery that the frequency of prophylactic and therapeutic tracheotomy is today in many clinics almost a daily occurrence The indications are of such vital importance and the necessity frequent enough to justify grouping in one paper most of the major conditions that may require tracheotomy before or during surgery

Tracheotomy is indeed an ancient procedure Antyllas, an outstanding surgeon living in the second century, described in detail the operation of tracheotomy Paulaus Aegeneta, a Greek practitioner of great repute, describes and devotes considerable space to tracheotomy in his Epitome of Medicine, published in the seventh century [1] These workers were followed by others, each of whom independently described, improved, and used tracheotomy in treating different maladies Avenozar, famous Cordovan physician, recommended its use in special cases of "laryngeal obstruction and impending suffocation " This was in the tenth century In 1610, during the Naples epidemic of diphtheria, Marco Aurelio Severino, a famous surgeon, repeatedly practiced tracheotomy Bretonneau, at Tours, first successfully performed tracheotomy for croup in 1825 In Paris, in 1831, Armand Trosseau, who was especially concerned with tuberculosis of the larynx, was the first to use tracheotomy in treating this disease [1 2] With the advance of surgery, the technic of doing tracheotomy has improved, as has the concept of its postsurgical care Along with these advances has been the extension of its applicability in varied surgical and medical conditions

The surgical conditions to be mentioned are indicative of specific and, at times, taxing problems as they relate to the field of anesthesiology In a treatise on maxillofacial surgery, the author describes indications for tracheotomy as follows (1) Acute respiratory obstruction which is already present but cannot be relieved by other means, and (2) respiratory obstruction which is not yet present but may occur either during or after operation [3] The latter two concepts, it will be noted, can be adapted to any surgical problem that compromises the patency of the proximal airway Patients presenting conditions which necessitate tracheotomy, as conceived by the first indication, are seldom, if ever, denied this life-saving procedure The need in these cases is obvious, it is urgent, it is mandatory On the other hand, the second indication, it is felt, is oftentimes ignored since the need for tracheotomy in these patients is so frequently insidiously concealed And yet, it is this latter category that is more numerically represented in our clinics and operating pavilions

The following is believed to be a practical classification of surgical conditions which may and usually do require tracheotomy as a means to maintain the airway

1 Cases presenting neoplasms in, or in proximity to, the upper respiratory tract

2 Cases presenting severe, moderately severe, and spreading infection involving the pharyngeal, laryngeal, or neighboring structures

3 Cases in which, as a result of injury or severe trauma, the anatomic architecture of the upper air passages becomes distorted or destroyed

In contemplating tracheotomy in these patients, the problems are not always merely to recognize and establish the need for this procedure One must also determine the period in which tracheotomy should be performed These considerations are valid not only because they have a direct bearing on the life and welfare of the patient, but also because they may either facilitate or increase the difficulties of surgery and aid or prove detrimental to anesthesia

The most common condition, in the first group of our classification, is carcinoma of the larynx requiring total laryngectomy [4] Here it is felt that these patients do best when subjected to a preliminary tracheotomy prior to definitive surgery In addition, it is recommended that those patients who have suffered a chronic partial obstruction and who suddenly develop an acute obstruction of the airway should be permitted

Presented at the 143rd Annual Meeting of the Medical Society of the State of New York, Buffalo Section on Anesthesiology May 4 1949

Published with the permission of the Chief Medical Director, Department of Medicine and Surgery Veterans Administration, who assumes no responsibility for the opinions expressed or conclusions drawn by the authors.

about one week of post-tracheotomy convalescence before surgery, with the view of correcting the unbalanced physiology usually present in these cases.[5] Generally speaking, when a preliminary tracheotomy is established, the problems besetting the patient, surgeon, and anesthetist are simplified.[6] A sterile endotracheal tube with an inflatable cuff is inserted into the tracheostomy by the surgeon. The other end of the tube is connected to the anesthesia apparatus by the anesthetist. To facilitate the introduction of the tube and to increase the tolerance of the patient to the tube, cocainization of these areas has proved satisfactory. Inhalation anesthesia is then effected, and surgery is performed. When the lesion is not large and the airway is not obstructed, many authors prefer initial transoral or transnasal endotracheal intubation following the induction of anesthesia.[7-8]

The surgeon proceeds until the larynx is completely mobilized from its surrounding structures and the site of severance of the larynx from the trachea has been elected. The endotracheal tube is then withdrawn under direct vision by the anesthetist to a point which will allow the surgeon to sever the trachea completely. The roof of the trachea is next grasped and brought into the wound margins in the neck. Finally, the endotracheal catheter is completely withdrawn, and a sterile endotracheal tube is used, as described earlier. Surgery is then completed. A modification of the latter method is to perform a classic tracheotomy just before the severance of the larynx and utilize the tracheostomy to pass an endotracheal tube through which inhalation anesthesia is continued.

A different approach is to perform laryngectomy under regional anesthesia, with bilateral deep and superficial cervical block. A tracheotomy is then done at the close of the operation. This method has been reported as being satisfactory by some workers.[9] Nevertheless, it is felt that this method unnecessarily subjects the patient to undue psychic trauma, pain, and varying degrees of hypoxia. The latter objectionable features are especially true, both in the early stages of surgical intervention when laryngeal obstruction may be prominent and in later stages of the operation when blood and secretions may accumulate. These methods are adaptable to all degrees of radical head and neck surgery including massive carcinomatous lesions of the oral and cervical regions. Large intrathoracic goiters and malignancies of the thyroid gland can prove especially hazardous and complex problems.[10]

A word of caution is added concerning the use of preliminary transoral or transnasal endotracheal tube in handling these problems. The danger of dislodging necrotic neoplastic elements during intubation and causing mechanical metastatic extension in more distal areas of the respiratory tract is ever present. One should also keep in mind that these same friable pieces of tissue that may break off can cause sudden and fatal respiratory obstruction.

In our service a total of 11 total laryngectomies and four mandibulectomies were done in a period of two years. In four of these a first-stage tracheotomy was done about one week prior to definitive surgery. Four were done using a transoral endotracheal tube during the early stages of the procedure, followed by a tracheotomy some time before the termination of the operation. Seven were anesthetized with regional or local methods followed immediately by a tracheotomy, and the operation then continued with anesthesia supplied through a sterile tube as described earlier. There was one death in this series.

Case Report

This fifty-two-year-old man was admitted to the hospital with a diagnosis of extrinsic carcinoma of the larynx. Signs and symptoms of respiratory obstruction had been present for two months prior to admission. The patient was scheduled and brought to surgery. Before the induction of anesthesia the blood pressure was 110 systolic and 70 diastolic. The pulse rate was 64 per minute, respirations 24. A control electrocardiogram indicated a normal tracing. At 8 32 A.M. induction of anesthesia was commenced with nitrous oxide and oxygen, using a 4 1 mixture. At 8 50 A.M. the patient was receiving nitrous oxide, ether, and oxygen mixture. Serial electrocardiogram tracings during this period showed an increase in cardiac rate. The patient was exhibiting a rather prolonged excitement stage and disturbing degrees of cyanosis.

In order to shorten the time interval of the latter two objectionable elements, 60 units of curare (d-tubocurarine, 20 units per cc.) were given intravenously at 8 52 A.M. The patient was noted to be apneic shortly thereafter and was intubated at 8 56 A.M. An attempt to administer procaine intravenously at this time was unsuccessful due to vasomotor collapse. At intubation the patient was completely relaxed. The mucous membrane was intensely cyanotic. No reaction to the tube was noted. The tissues were without tone. Approximately one minute after intubation 100 mg. of procaine were given intravenously. At 9 03 A.M. the abdomen was opened, and cardiac massage begun. Along with these, other heroic measures and stimulant drugs were tried in an attempt to revive the patient. All measures proved to no avail. It was felt that this patient, who had been suffering from the effects of chronic hypoxia, succumbed when subjected to a bout of acute asphyxia. No postmortem was done.

In the second group—those patients presenting moderately severe, severe, and spreading infection of the oral, pharyngeal, and laryngeal struc-

tures—regardless of the degree of patency of the airway existing before surgery, it is obligatory that preliminary tracheotomy be done If this is not done, many of these patients, because of the loss of conscious effort and relaxation of anatomic structures that occur during induction of anesthesia, will obstruct easily and some times fatally Add to this the ever-present hazard of severe laryngospasm, a reflexogenic element notoriously prominent and sensitized in the presence of inflammation of neighboring structures Should these disagreeable complications not occur, the edema of surgical manipulation and inflammation, present postoperatively, will often encroach on the airway and will usually require an emergency tracheotomy The latter, for the most part, are done under the most adverse conditions The most common surgical category exemplifying these hazards is Ludwig's angina [12]

In the third group of our classification the hazards encountered embrace some elements described earlier, plus those peculiar to the inciting cause Primarily, this group comprises maxillofacial surgery, necessitated as a result of severe wounds of the head and neck.[3–13]

Respiratory obstruction may accompany the following conditions (1) multiple fractures of the mandible with resultant malposition of the tongue, (2) presence of foreign bodies encroaching on the air passages, (3) destructive wounds of the base of the tongue, pharynx, or larynx, (4) extensive soft tissue injury of facial and cervical elements with spreading infection, (5) destruction of or injury to the motor innervation of the larynx, and (6) penetrating wounds of the neck with concomitant injury to pleura, thorax and pneumothorax, or mediastinal emphysema

The challenge offered to surgeon and anesthetist by some of these problems at times appears insurmountable The variable degree of destruction of vital upper respiratory anatomic structures in these patients magnifies the urgency and the technical difficulties confronting the surgical team The existing infection or the postoperative secondary infection offers additional dangers to all concerned

Many of these patients will apparently have adequate airways following their injury, nevertheless, it is advocated to do a preliminary tracheotomy in all instances The inherent pitfalls subsequent to failure in using tracheotomy in these patients are many and varied

To cite an example, the patient with a piece of shrapnel lodged and fixed near the larynx or between the tongue and the pharynx may show no sign of respiratory distress, but, upon removal of this foreign body, the injured and devitalized soft tissue, lacking the normal anatomic support, may collapse and fatally obstruct the airway The potential danger of postoperative edema and inflammatory reaction compromising the airway in these patients is again mentioned In this group the best results have been obtained by doing a tracheotomy under local anesthesia and then following through with transtracheal general anesthesia

It should be understood that tracheotomy and the use of an endotracheal tube in the categories described herein is not an absolute assurance of an adequate airway The lower airway must at all times be kept free of mucus and hemorraghic secretions that may slip down past the inflated cuff or that may be formed in the bronchial structures In keeping with this consideration, a suggestion that is believed to be a refinement in technic is mentioned In operating on these patients the surgeons should be stationed at the head end of the operating table, and the patient should be placed in a moderate Trendelenburg position This will help considerably in keeping anesthetic tubing and apparatus out of the surgical field and will materially aid the gravitation of secretions and blood from the lower respiratory tract

Summary

Prophylactic and therapeutic use of tracheotomy in some major surgical conditions has been presented with a view to maintaining an adequate airway during all stages of surgery and anesthesia

The indications requiring tracheotomy have been reviewed

The pitfalls, complications, and potential fatalities because of failure to recognize the need for tracheotomy in the face of a seemingly adequate airway have been offered

It is believed that these measures will help in protecting the life and welfare of the patient, facilitate the difficult task of surgery, and aid in the conduct of physiologic anesthesia

Discussion

Harold F Bishop, M D, *Valhalla*—Dr Friscia is to be congratulated for re-emphasizing the importance of employment of tracheotomy as a means of a more adequate control of the airway for operations in and about the upper respiratory tract

In the past, tracheotomy has been considered more or less as a life-saving procedure which was carried out when mechanical obstruction of the airway had developed to an advanced degree In this capacity it has often proved to be a heroic, futile endeavor As Dr Friscia has pointed out, emphasis should be placed on the utilization of tracheotomy as a prophylactic means of maintaining the airway Trauma, infection, and malignant lesions located about the upper airway may seriously distort the respiratory tract by edema, swelling, and loss of anatomic structure. In the presence of such surgical lesions it often may be advisable to perform tracheotomy prior to operation particularly if the contem-

plated surgery is to be extensive and radical in nature

Frequently, it may become necessary to employ tracheotomy in certain problems of resuscitation, and here again it should be regarded as a measure that is carried out early in the course of treatment In dealing with anterior poliomyelitis of the bulbar type, the swallowing and cough mechanisms are disturbed to such a degree that it becomes difficult to keep the respiratory tract free from secretions In such patients during the past season it has been observed that tracheotomy, performed shortly after admission to the hospital, has been of immeasurable value in the management of these patients while they are confined to the Drinker respirator A rubber tube has been attached to the tracheotomy opening and led to the outside of the respirator through the rubber collar Such an arrangement provides for a means of oxygenation and frequent tracheal aspirations without interrupting the action of the respirator

During the past year tracheotomy has been carried out on ten occasions in dealing with the resuscitation of patients This group includes six patients with bulbar poliomyelitis, one patient with barbiturate poisoning, vomiting, tracheal aspiration, and laryngeal edema, one patient with myasthenia gravis in crisis, one patient with laryngitis and edema following intubation, and one patient with thoracic transverse myelitis who developed massive pulmonary atelectasis The results in these ten patients have been gratifying, and for this reason we will continue to recommend early tracheotomy in similar instances

NEW YORK STATE MEDICAL LIBRARY

Doctors of New York State are reminded of the facilities of the State Medical Library at Albany They are invited to visit, telephone, or write to the Library where a trained staff of librarians will take care of their requests

Upon request, a copy of the regulations will be sent, which lists the services of the Library, including the compiling of bibliographies, sending material on specific subjects, or filling requests for definite book or journal references

A collection of over 57,000 books and the receipt of approximately 600 current medical journals enable the Medical Library to offer a real service to the doctors of the State

Letters may be addressed to Miss Maude E Nesbit, Librarian, New York State Medical Library, Education Building, Albany 1, New York.

USE OF INTRAVENOUS QUINIDINE DURING CLINICAL ANESTHESIA FOR TREATMENT OF ACUTE ARRHYTHMIAS

VINCENT J COLLINS, M D , New York City

(From the Department of Anesthesiology, St Vincent's Hospital)

THE PROBLEM of cardiac arrhythmia presents itself to all anesthetists at one time or another The clinical recognition of arrhythmias, particularly with cyclopropane, occurs in about 7 to 10 per cent of the cases, according to Taylor [1] Actually, with cyclopropane arrhythmias occur in about 48 per cent of the cases, as shown by the electrocardiographic studies of Kurtz [2] Fortunately, most are not serious, but they may be converted to serious disorders of rhythm Very often the development of an arrhythmia may turn the balance against a patient undergoing major surgery For instance, it has been shown that auricular fibrillation may decrease the cardiac output 35 to 40 per cent, while gas studies show that a less efficient cardiorespiratory function exists during arrhythmia [3,4] On the other hand, restoration of an arrhythmia to a normal mechanism increases cardiorespiratory function and also increases vital capacity [5]

To control arrhythmias, various measures have been utilized Francois-Franck used cocaine derivatives intravenously to control disorders of rhythm [6] Beck employed the epicardial application of procaine and Metycaine to control arrhythmias during thoracic surgery [7] This same technic was shown by Mautz to raise the resistance of the heart to the development of disordered rhythm [8] Electric countershock has also been employed to control ventricular fibrillation by both Beck and by Fauteux [9–11] Milowsky and Rovenstine recommend ether to control the abnormalities of rhythm occurring during cyclopropane anesthesia [12] Burstein reported the use of intravenous procaine to control cyclopropane arrhythmias in dogs and showed the value of this drug for the treatment of acute arrhythmias in man [13,14] Until the present time, this has been the most efficacious procedure

Although Wiggers found that procaine administered to dogs raised the resistance of the ventricles to fibrillation, he found no instance in which the heart became entirely refractory to fibrillation [15] Fauteux also found experimentally that procaine could not always prevent fibrillation when given intravenously [11] This worker recommended the injection of procaine into the auricular appendage, and when combined with electrical countershock, plus cooling of the myocardium, there was a greater success in the restoration of regular cardiac activity

Many anesthesiologists have also experienced clinical failure of procaine to restore regular cardiac rhythm In view of this and the experimental work above, we chose quinidine as a drug to be given intravenously for the control of arrhythmias Since the trials in man have been successful in treating disordered rhythms occurring during anesthesia, a program of prophylactic oral administration of quinidine is now being carried out as a part of preanesthetic medication whenever cyclopropane is to be administered and will be reported at a later date

Method and Material

The technic and results in treating acute arrhythmias with intravenous quinidine are herewith presented A 1 per cent quinidine sulfate solution in distilled water was first employed Since this is the limit of solubility of this salt, a more soluble preparation was desired Quinidine lactate is such a salt and has been found to be equally effective as the sulfate salt compound * The technic consists in the injection of from 0 2 to 0 4 Gm of the quinidine lactate intravenously as soon as a disorder of rhythm is diagnosed

Records on the first 25 cases so treated during anesthesia induced for a variety of surgical procedures were analyzed and form the basis of this report The disordered rhythms were diagnosed entirely on clinical grounds and were situations where procaine, which would ordinarily have been used, was not used, except in two instances These arrhythmias included tachycardia, extrasystoles, bigeminal rhythm, and complete dysrhythmia In all cases quinidine was beneficial Improvement in rhythm was evident within five minutes, and complete restoration to regularity was usually observed within eleven minutes The anesthetic agents employed in the 25 cases were as follows ether oxygen, seven, cyclopropane oxygen, 14, cyclopropane-oxygen-ether mixture, one, and pentothal, three

Of these anesthetic procedures it is noted that arrhythmias developed during pentothal anes-

Presented at the 143rd Annual Meeting of the Medical Society of the State of New York Buffalo Section on Anesthesiology May 5 1949

* Quinidine lactate was furnished through the courtesy of Eli Lilly and Company for investigational use.

thesia in three cases Two of these anesthetics were administered for eye enucleations, while the third was for laminectomy of the fourth to seventh thoracic vertebrae It is presumed that the operative procedure itself acted as the initiating factor in these cases, not necessarily the anesthetic agent Primary interest, however, is with the cases receiving cyclopropane In two of these cases, the use of procaine failed to restore cardiac rhythm to normal within the time usually allotted for such action, this generally being less than two minutes, but quinidine lactate was effective Two cases are summarized here, together with a third case for which electrocardiographic tracings are available

Case Reports

Case 1—E D, a thirty-year-old married woman with an acute abdominal condition, came to the operating room for emergency operation The preoperative diagnosis was ruptured ectopic pregnancy Temperature was 100 6 F, pulse 88 and regular, and respirations 22 Induction and maintenance of anesthesia was with cyclopropane and oxygen Eight minutes after start of anesthesia a coupled rhythm developed with a rate of 140 per minute Procaine, 100 mg intravenously, was given rapidly as soon as the diagnosis was made Little effect was noticed, and in five minutes another 80 mg of procaine was administered intravenously In the next five minutes rhythm became totally irregular, whereupon 0 3 Gm. of quinidine lactate was injected intravenously In seven minutes rhythm was regular, and in ten minutes rate was 88 per minute Throughout the remaining seventy-five minutes of surgery, rhythm remained regular, although cyclopropane was continued even to a depth where controlled respiration was used.

Case 2—J T, a thirty-seven-year-old woman with a diagnosis of active pulmonary tuberculosis, submitted to right pneumonectomy Preanesthetic medication consisted of oral Seconal, 0 1 Gm. two hours preoperatively, and subcutaneous Demerol, 75 mg with 0 4 mg of scopolamine seventy-five minutes preoperatively Induction with cyclopropane was smooth and rapid Further anesthesia then consisted of an ether-cyclopropane mixture Intubation was attempted under vision with McIntosh laryngoscope, but exposure was poor and hence a number 35 French Magill catheter was introduced by blind nastrotracheal technic Pharynx was packed, and a closed to-and-fro carbon dioxide absorption system was set up with the patient in the left lateral position Surgery began twenty minutes after start of anesthesia Respirations were compensated throughout most of the procedure One hour after surgery began, a dysrhythmia was detected and a fall in blood pressure noted Procaine, 90 mg, was given intravenously and a second dose of 100 mg injected in five minutes Pulse rate was between 120 and 180 and rhythm completely irregular Observation of the heart at this time showed the auricles to be fibrillating and the ventricles to be responding irregularly Surgery was suspended Because nine minutes had elapsed since the first injection of procaine without improvement, 0 3 Gm. of quinidine sulfate was given intravenously and 0 1 Gm intramuscularly Rhythm improved and was completely regular in six minutes although rate was rapid At the end of eleven minutes tachycardia disappeared, and rhythm was completely regular, although cyclopropane was continued as needed

Case 3—E A, a twenty-nine-year-old woman, arrived in the operating room for myomectomy She received morphine sulfate 10 mg and scopolamine 0 4 mg subcutaneously one and a half hours before anesthesia Induction and maintenance of anesthesia were with cyclopropane and oxygen, and a closed to-and-fro carbon dioxide absorption system was employed. A tachycardia developed about fifteen minutes after the start of anesthesia, while the surgeon was doing a preliminary dilatation and curettage Electrocardiographic equipment was arranged and tracings made. The anesthesia was lightened so that airway had to be removed, and tachycardia disappeared, occasional extrasystoles remained As soon as anesthesia was deepened to second plane of stage III anesthesia, a tachycardia developed which was replaced by a continuous run of ventricular extrasystoles At this point 0 25 Gm of quinidine lactate was administered intravenously Tracings were made every thirty seconds At the end of three minutes, only occasional extrasystoles were present, and a completely regular rhythm supervened in four and a half minutes at a rate of 100 beats per minute. At the end of five minutes the rate was 72 beats per minute No abnormalities of rhythm were further noted, even though deep cyclopropane anesthesia, accompanied by controlled respiration, was used for peritoneal closure

Discussion

Originally, it appeared from clinical observation that quinidine administered intravenously was effective in about ten to twelve minutes However, examination of the electrocardiographic tracings reveals that many rhythms are reverted to normal in four to six minutes Frequently a tachycardia, similar to the paradoxic tachycardia following the slowing of an auricular fibrillation, develops and lasts for one to three minutes [16]

No untoward cardiovascular reactions have been noted at the time of administration, and in fact there has been improvement with elevation of the systolic blood pressure Neither has respiratory depression or bronchospasm been seen in the cases treated No instances of idiosyncrasy have been detected in a careful postoperative follow-up

The use of quinidine, particularly its intravenous administration, has been avoided by many physicians because of its reputed marked toxicity Much of this feeling has apparently developed on theoretic grounds, especially in

relation to patients with chronic auricular fibrillation The most feared reaction is that of embolism. For this to happen auricular fibrillation must have existed for some time in order that a thrombus form Stroud and Laplace state that the incidence of embolic phenomenon in chronic auricular fibrillation is no greater with quinidine than with digitalis [17] Marvin reports that embolic episodes are definitely less when quinidine is used than when no drug is administered [18] Likewise the report by McMillan in which patients with chronic auricular fibrillation were treated with quinidine shows that serious side reactions to quinidine are few [5] In other words, it appears that toxic reactions to quinidine have actually been overrated and a useful drug has been neglected Furthermore, the arrhythmias developing during anesthesia are acute, and hence thrombus formation is minimal or unlikely The precipitation of ventricular fibrillation by quinidine is a possible hazard However, quinidine is actually indicated for breaking the mechanism of paroxysmal ventricular fibrillation [16]

Summary

Quinidine preparations have been found effective clinically in treating disorders of cardiac rhythm occurring during anesthesia especially with cyclopropane A highly soluble salt, quinidine lactate, has been tested and found to possess the same activity as the sulfate salt A program of preanesthetic medication with oral quinidine is being carried out as a prophylaxis against the development of arrhythmias

6,597 DOCTORS ADDED TO MEDICAL PROFESSION IN 1948

Doctors entering the ranks of the medical profession in 1948 number 6,597, according to the 47th annual report of the American Medical Association Council on Medical Education and Hospitals The figures show that 3,230 doctors in this country died in 1948 The net increase in the physician population of the United States during 1948 was 3,367

Medical examining boards of the 48 states and of the District of Columbia, Alaska, Hawaii, and Puerto Rico issued 13,551 licenses to practice medicine during 1948 Of this number, 94 per cent went to graduates of approved medical schools, 5,967 were granted after examination, and 7,584 were granted by reciprocity and endorsement of state licenses or the certificate of the National Board of Medical Examiners The number of licenses issued in 1948, as in two previous years, was greater than in any prewar year Although in 1948 there were 892 fewer licenses registered than in 1947, there were increases recorded in 22 states, nearly all rural The greatest number of licenses in 1948 were issued in California, 1,751 New York licensed 1,385, and Illinois licensed 749 More than 500 physicians were licensed in Ohio, Pennsylvania, and Texas, and no state licensed fewer than 25

Candidates appearing before medical examining boards numbered 6,560, of whom 5,840 passed and 720 failed The candidates represented 70 approved medical schools of the United States, nine approved schools of Canada, four medical schools in the United States now extinct, 107 faculties of medicine, and three licensing corporations of other countries, five unapproved institutions, and six schools of osteopathy The greatest percentage of failures represented three groups foreign schools, unapproved schools, and schools of osteopathy In these groups 51 5, 42 7, and 37 8 per cent, respectively, failed From the United States approved schools there were 3 3 per cent who failed, as did 16 5 per cent of the Canadian graduates and 6 7 per cent of the graduates of extinct schools —*J A M A 1, May 21, 1949*

THE RECOGNITION AND MANAGEMENT OF CARDIAC AND CIRCULATORY EMERGENCIES DURING ANESTHESIA

S R Masiello, M D , and A A Lombardi, M D , New York City

(From the Departments of Anesthesia and Medicine, New York Medical College and Flower and Fifth Avenue Hospitals)

THE onset of acute cardiac or circulatory emergencies during the course of an anesthesia is a not too infrequent occurrence The very nature of such accidents demands early diagnosis and treatment which, at times, if incorrect, may be of equal harm to the patient Unfortunately, there is an understandable tendency whereby the anesthetist may become respiration conscious to a point that relegates a patient's cardiocirculatory status to one of secondary importance Admittedly, there is a distinct disadvantage to these emergencies when we couple the facts of an unconscious patient, lack of subjective symptoms, and technical diagnostic facilities with that of concomitant surgery which may or may not be discontinued Since it is assumed that these accidents definitely fall in the sphere of the anesthesiologist, the thought is entertained that some help may be derived from a review of the subject Consideration therefore is directed toward the following points choice of anesthesia, so-called nonacute states, reflex cardiac and circulatory accidents, acute cardiac emergencies, and treatment

Choice of Anesthesia

A full review of this topic is beyond the scope of this discussion [1] However, a few comments do seem pertinent

Cardiologists and most anesthetists agree that ether is usually the agent of choice in cardiac patients [2] This is mentioned by way of remarking on a less widely held technic, i e , an attempt to evaluate a cardiac status in terms of cyclopropane anesthesia One may concede its use for induction in most cases except perhaps the severe cardiac However, its continued use is not justified in the face of minor deviations in pulse and blood pressure The transition from such minor infractions on circulation to those of major proportions can be extremely rapid in patients with an already pathologic circulatory system Since we can safely assume that the highest incidence of accidents will occur in established cardiacs, it seems definitely unwarranted to submit these patients to a possibility not beyond some control of the anesthetist

Similar comments are applicable to entities other than strict cardiacs, but it is thought best to mention these in discussing the specific problems

Nonacute States

This group has reference to four main points extrasystole, bradycardia, tachycardia, and sustained hypertension or hypotension Conceivably, one could be inclined to discard these alterations as unimportant since they infrequently result in serious pathology On the other hand, neglect to observe the above-mentioned irregularities will not facilitate the ability to diagnose arrhythmias or accidents of serious consequence

Extrasystole —Recognition is simple Of importance is the fact that extrasystoles are due to a focus of irritation and may well be forerunners of major pathology The commonest causes during inhalation anesthesia are hypoxia and cyclopropane Correction of the former is rarely difficult In the case of cyclopropane, addition or, if necessary, substitution of ether usually suffices to correct the arrhythmia [3] If the condition persists, then the possibility of more profound pathology should be constantly entertained

Bradycardia.—In the normal patient a pulse of sixty or less should constitute bradycardia If associated with a transient hypertension, it may indicate a compensatory phase of circulation If alone, however, bradycardia is best considered as vagal in origin, resulting either from parasympathomimetic drugs or reflex stimulus The former is usually relieved by a change of agent plus atropine intravenously, $^1/_{100}$ to $^1/_{50}$ grain Bradycardia due to reflex stimulus may be more persistent, although treatment is the same Beyond this point, continuation of a slow pulse demands consideration of heart block

Tachycardia —It is less simple to determine when a pulse reaches this category so that individualization becomes necessary We are not concerned here with the shock picture but only with a simple tachycardia whose importance lies in the associated factor of a myocar-

Presented at the 143rd Annual Meeting of the Medical Society of the State of New York Buffalo Section on Anesthesiology May 5 1949

dium suffering insult Etiology and treatment can be listed as follows

Etiology	Treatment
1 Anesthetic agent	1 Change drug employed
2 Light anesthesia with sympathetic stimulation	2 Proper depth of anesthesia
3 Excess carbon dioxide	3 Correct obstruction acidosis, or inefficient filter
4 Prolonged deep anesthesia	4. Lighten plane of anesthesia if possible Use curare
5 Thyrotoxicosis	5 Gynergin, 0 5 mg, intravenously [4] Terminate surgery if necessary
6 Hypoxia	6 Adequate oxygen
7 Fluid loss (not blood)	7 Saline infusion

Morphine sulfate, $^1/_6$ to $^1/_{10}$ grain intravenously, has been claimed efficient in controlling a tachycardia We hesitate to recommend its empiric use in this manner, much the same as we do any drug during a state of disturbed physiology

Sustained Hypertension and Hypotension.—A sustained progressive rise in pressure, especially in the older age group, entails the possible complication of cerebral accidents It also creates a difficult operative field because of excessive bleeding and in brain surgery can produce severe enough intracranial pressure to prohibit surgery Commonest causes and treatment include the following

Cause	Treatment
1 Agent—cyclopropane especially	1 Substitute or add ether
2 Excess carbon dioxide	2 Correct obstruction, change filter, combat acidosis
3 Light anesthesia	3 Proper depth of anesthesia
4. Hypoxia	4 Insure adequate oxygen
5 Thyrotoxicosis	5 Gynergin. Terminate surgery if necessary

Hypotension is not a common complication if shock and reflex activity are excluded It is no less important, however, because of the subsequent hypoxia and possible postoperative thrombosis One may anticipate its occurrence and employ therapy as follows (1) Hypotension due to Avertin should be followed with oxygen, saline infusion, and Neosynephrine [5] (2) Fluid loss from perspiration should be treated with saline infusion

Reflex Cardiac and Circulatory Accidents

Undoubtedly, reflex accidents produce more cardiac and circulatory derangements during anesthesia than any other single causative factor An awareness of the possibility of such reflex activity constitutes an integral part of efficient anesthesia Obviously, recognition of the entity is facilitated primarily by considering the area involved, and on this basis most discussions of reflex activity have anatomic designation

Head and Neck.—Vago-vagal and carotid sinus reflexes are the prime offenders from this area of the body

Vago-vagal reflexes may be initiated by surgical or anesthetic manipulation [6] One should bear in mind that light anesthesia enhances the occurrence of the vago-vagal syndrome which is often associated with endotracheal technic It is advised especially that extubation be done slowly and not during light anesthesia Further, if by chance a vagotonic element in the patient is known to exist beforehand, then the use of parasympathomimetic drugs is ill advised, and adequate atropinization is recommended in premedication

Symptomatically the syndrome may exhibit itself in varying degrees of intensity involving respiration and circulation The most common noted are a sudden onset of respiratory difficulty progressing to apnea, cyanosis, slow to absent pulse, dilated pupils, and low or absent blood pressure, or an extremely rapid onset of bradycardia and cardiac standstill. In the first mentioned, treatment should include the following (1) artificial respiration, (2) atropine, $^1/_{50}$ to $^1/_{75}$ grain, intravenously, (3) removal of stimulus (except for endotracheal tube), (4) caffeine sodium benzoate, 7½ grains, and (5) curare, 1 to 3 cc , may be considered as a final therapeutic means

The second type with cardiac standstill offers greater difficulty Atropine or curare is of little value Artificial respiration should be instituted and cardiac resuscitation contemplated immediately

Carotid sinus reflexes may be initiated in somewhat similar fashion [7] The commonly ascribed causes include pressure or traction as from surgical retractors and anesthetic head straps Not infrequently, these patients may be known to have a hypersensitive sinus preoperatively, and what has been said about vago-vagal reflexes in this light is applicable here Ability to block the sinus with procaine offers a distinct advantage, however [8] Occurrence during anesthesia is recognized in two types one with slow pulse and low pressure, the second with a precipitous drop in pressure Treatment consists of removal of the stimulus, atropine intravenously, and curare.[8]

Thoracic —During intrathoracic surgery the onset of vagovagal reflexes, as discussed above, constitutes the foremost accident to anticipate [9] The higher incidence of pulmonary surgery naturally creates a relatively greater occurrence of these accidents during such procedures Consequently, cardiac resuscitation is most often reported in connection with pulmonary surgery, and a few pertinent comments seem justifiable Resuscitation should be instituted immediately in the face of cardiac standstill, artificial respiration being part and parcel of the procedure, procaine seems indicated only if and when spontaneous action returns and especially if it be fibrillatory in nature, adrenalin and analeptics have not yet been proved advantageous [10 11]

Cardiac surgery is almost a distinct entity as far as the problem of reflex activity is concerned [12 13] What has been said above is applicable, but, in addition, some unusual syndromes have resulted from cardiac manipulation Palpation of the myocardium during cardiopericardiopexy has been known to cause a complete absence of blood pressure which seems best attended by Paredrine [14] Ligation of a patent ductus may be accompanied by a marked change in pulse pressure The literature is continuously adding facts to this relatively new anesthetic problem in surgery for congenital cardiac defects which is a distinct challenge to the surgeon and anesthetist

Sympathectomy for hypertension is best considered here also The first stage of this procedure is not often associated with any difficulty The second stage, however, is commonly associated with a great fall in pressure on section of the chain Vasoconstrictors and fluid, preferably blood or plasma, are essential in combating this fall One ampule of Neosynephrine in 500 cc of saline may be used, and usually it is best to have this available on a Y tube setup with normal saline to insure an intravenous route Blood can then be immediately placed on the infusion stand

Abdominal —Traction reflexes is the term usually applied to those arising in the abdomen, and, of these, the coeliac plexus reflex is the foremost [15] It may be due to traction or pressure and is recognized by a sudden unexplainable fall in blood pressure, slow or absent pulse, and ashen-gray color Removal of the stimulus should be the first consideration Further therapy cannot be set forth with certainty except perhaps for splanchnic blocks, easily done intra-abdominally [16] One may also try prostigmine, atropine, or curare intravenously

Rapid gastric dilatation can initiate a vagal reflex associated with coronary spasm and cardiac arrest [17] A similar picture is observed with severe pulmonary embolus One should note that this differs from the vago-vagal type of reflex which affects the conducting mechanism of the heart

The syndrome of rapid gastric dilatation may result from an anesthesia accompanied by obstruction and increased pressure or even from an apnea technic without intubation Fortunately it flashes a storm warning—rigid abdominal musculature despite otherwise adequate depth of anesthesia—and this is most important Other symptoms include ashen-grey cyanosis, rapid feeble pulse, and drop in blood pressure

Management of this emergency is simple but must be rapid It consists of insertion of a large stomach tube to deflate the stomach Atropine, $^1/_{50}$ to $^1/_{75}$ grain, may be given intravenously to offset vagal action

A good many other reflex effects on circulation may also be instigated in the abdomen, and a brief enumeration is deemed advisable

1 Traction or pressure in the pelvis or perineum may produce effects parasympathetic in nature with a fall in pressure Treatment involves removal of the stimulus and atropine

2 Sudden removal of a large tumor or fluid mass may cause a shocklike picture and is best treated with fluids intravenously

3 Clamping or ligation of large vessels may give rise to a shocklike syndrome The picture is transient and responds to supportive therapy

4 Removal of adrenal medulla tumors, pheochromocytomas, is attended by a severe fall in pressure which is preceded by a marked rise during manipulation Choice of anesthesia has no relation to the outcome Treatment consists of vasoconstrictors in large doses and blood or plasma

Miscellaneous

1 *Extremities* —Release of a tourniquet, especially on the lower limbs, may precipitate a marked fall in pressure, rapid pulse, and a cold, clammy patient Treatment is supportive, oxygen and fluids primarily

2 *Position* —Postural changes causing circulatory derangements are well-known entities [18] The commonest occur with the use of a kidney rest or gallbladder brace The onset is rapid, and one sees a low or absent pressure, weak pulse, and an ashen-gray or cyanotic patient Removal of the elevated rest usually suffices but may be supplemented with atropine intravenously

3 *Peripheral Dilatation* —This is an unusual picture, the true cause of which is un-

known, since it has been observed with more than one type of inhalation agent and with or without obvious stimuli. The symptoms, however, are definite and easily described. Usually the first sign noted is a peculiar oyster-gray color, despite seemingly adequate exchange. Blood pressure cannot be auscultated but may be palpated, and the pulse has a distinct absence of tension. The response to atropine intravenously is dramatic and heartening.

Acute Cardiac States

Coronary.—Briefly, the picture is one of shock with no explainable cause. There is always a rapid thready pulse. One might say that unexplainable shock during anesthesia should be considered as arising from coronary disease and proper therapy instituted. This should include (1) high oxygen administration, (2) consultation relative to the earliest possible termination of surgery, (3) elimination of all inhalation anesthetics except ether, (4) morphine if patient is conscious, (5) if pressure remains low, one unit of blood or plasma may be given slowly, (6) caffeine sodium benzoate, 7½ grains, for stimulation, and (7) heparin, 50 mg., may be given to prevent clotting.[19]

Heart Block.—Usually, the only sign is a persistent pulse rate of 30 to 50 per minute. Blood pressure more often remains normal, and final accurate diagnosis depends on electrocardiography. Since most of these cases have no associated heart failure, treatment is limited to the use of ether-oxygen anesthesia and careful observation.

Auricular Fibrillation.—An irregular regularity of rate with a pulse deficit speaks for auricular fibrillation. Unless associated with decompensation it does not ordinarily require stringent measures. The following may be considered: (1) ether-oxygen anesthesia, (2) procaine intravenously, 3 to 7 cc. of a 1 per cent solution, (3) dicumarol to prevent postoperative pulmonary embolus if quinidine is to be used therapeutically.[20]

Ventricular Fibrillation.—This entity is usually sudden and fatal. If one should be fortunate enough to suspect its onset from extrasystoles and thready tachycardia or else actually see it during intrathoracic surgery, then procaine is definitely indicated.[21] Equally important, the surgeon and anesthetist should prepare for cardiac resuscitation.

Acute Cardiac Failure.—Left heart failure with pulmonary edema is the more frequent type to expect. Signs and symptoms include low or normal pressure, weak rapid pulse, hyperpnea, cyanosis, and "wet respiration" with moist rales on auscultation.

Treatment is as follows: (1) oxygen under positive pressure with helium if available, (2) Cedilanid (a purified digitalis preparation), 4 cc. intravenously, and repeat with 2 cc. in one hour if necessary (Digitoxin, 4 cc., may be substituted), (3) caffeine, 7½ grains, intravenously, (4) rapid termination of surgery, and (5) if failure occurs during a continuous spinal anesthesia, one may contemplate an added dose to minimize right heart return.[22,23]

Fibrillation During Thyroidectomy.—The signs are as described above but usually are preceded by tachycardia and hypertension.

Treatment consists of oxygen, Gynergin 0.5 to 1.0 mg. intravenously, Lugol's solution, 40 to 60 drops in 500 cc. of saline, and barbiturates. (Pentothal-nitrous oxide anesthesia may be substituted for cyclopropane or ether.)

Summary

An attempt has been made to consolidate and review the common cardiac and circulatory emergencies that may arise during anesthesia. Treatment of these accidents as an integral part of the anesthetist's functions has also been outlined. Discussion could probably be advanced about some specific therapeutic agents mentioned. This, however, is not the most important aspect of the subject. Fundamentally, one goal is of prime significance, and that has to do with the thought that every anesthetist should, first of all, familiarize himself with the accidents that may occur and, in addition, formulate a plan of approach to their treatment so that precious time will not be lost.

Discussion

John H. Geckler, M.D., *Buffalo*.—This paper, I think, has accomplished its purpose here—it has freshened our knowledge of cardiovascular emergencies and the accepted means of combating them. Fortunately, most of us see very few of the more serious of these phenomena, but the danger is that we might get the idea that it can't happen to us and neglect to plan for possible use, unhoped for as it may be, of a quickly available method of treatment.

I can add nothing to what has been said about choice of anesthesia. However, once the choice has been made, it is wise not to be afraid to change it if the patient doesn't handle well. I am sure most of us at some time or other have been amazed at how well the patient may do on what we didn't consider at first the anesthetic of choice.

When I was a resident, these arrhythmias with cyclopropane, which were just classified as nonacute states, did not worry me. I believed with Guedel that they were present in a certain plane,

and either lightening or deepening the anesthesia would abolish them.[a] There were just two instances where relaxation was needed, and yet I thought it inadvisable to push the cycle till the arrhythmia disappeared. But, for several years now, I have had a rather prominent "yellow streak' connecting my dorsal vertebral spines I resort only to the more conservative measures that have been mentioned (adding or changing to ether or perhaps the use of procaine) It is not that I believe the theory of hypothalamic hyperactivity is not sound, I am just no longer stubborn enough to try to prove it at someone else's risk. Perhaps Dibenamine is going to prove to be the drug of choice to stop these and other arrhythmias A recent editorial in *Gastroenterology* by Dr Alvarez quite enthusiastically cites the work of a couple of good physiologists and calls it the best adrenolytic drug yet found[b] It might even be better in thyrotoxicosis than the ergotamine preparation that was mentioned

Vago-vagal and carotid sinus reflexes I do not see very often, although for a good while I used to anesthetize throats locally in the hope of avoiding the former during intubation

I recall one hypertensive case during a total gastrectomy that responded to nothing, and it later developed that one of the units of blood I gave was mismatched. I have been unable to determine for sure, since, whether it could have been the cause

The problem of cardiac resuscitation is still not settled for me Beecher reported, not so long ago, two cases where prolonged massage and multiple needle punctures were useless, but epinephrine injection resulted in cardiac action[c] Recently, another group reported a case where all measures failed until strong traction on the pericardium, incident to its intended opening, turned the trick[d]

When standstill or fibrillation occurs, it is always dramatic and often, as I know, when you least expect it Nicholson says that early diagnosis is the essential thing, not to waste too much time checking the position of a blood pressure cuff which up to that time had been workable[e] Let the surgeon help you check up if he can feel the heart or a large vessel and then, when it is not a false alarm, get started quickly on massage, procaine, and if there is no fibrillation, a small amount of epinephrine I agree with this idea

I have never been convinced that sudden removal of a large tumor or fluid mass could in itself cause shock. I think it is a traction reflex in the case of the tumor mass, but, just in case I'm wrong, I'm always ready to treat it One of the most confusing cases I recall was a coronary under anesthesia, all I could say was that something had happened that I could not explain Fortunately, it ended happily

Dr Masiello mentioned pulmonary embolus I have had two fatal ones so perhaps I m overconscious of them One of these I was called to see within a couple of minutes after a blood pressure fall which might have come from a traction reflex as a large uterus was pulled out of the abdomen, a tube which had just been inserted blindly, or the embolus, for she had been explored five to six days before and had every right in the world to thrombosed pelvic vessels

In summary, one might say about anesthesia as about most other things in life—if you know the trouble you might get into and are prepared to get out of it, you usually don t get in it

CORRECTION

In a "filler" on page 1162 of the May 15 issue of this JOURNAL, an unfortunate typographical error occurred The original clipping from a news letter of the American Medical Association mistakenly stated that shoe fitting fluoroscopes were "condoned,"—naturally the term shoud have been "condemned" We regret that this mistake was not noted by our editorial staff

known, since it has been observed with more than one type of inhalation agent and with or without obvious stimuli The symptoms, however, are definite and easily described Usually the first sign noted is a peculiar oyster-gray color, despite seemingly adequate exchange Blood pressure cannot be auscultated but may be palpated, and the pulse has a distinct absence of tension The response to atropine intravenously is dramatic and heartening

Acute Cardiac States

Coronary—Briefly, the picture is one of shock with no explainable cause There is always a rapid thready pulse One might say that unexplainable shock during anesthesia should be considered as arising from coronary disease and proper therapy instituted This should include (1) high oxygen administration, (2) consultation relative to the earliest possible termination of surgery, (3) elimination of all inhalation anesthetics except ether, (4) morphine if patient is conscious, (5) if pressure remains low, one unit of blood or plasma may be given slowly, (6) caffeine sodium benzoate, 7½ grains, for stimulation, and (7) heparin, 50 mg, may be given to prevent clotting [19]

Heart Block.—Usually, the only sign is a persistent pulse rate of 30 to 50 per minute Blood pressure more often remains normal, and final accurate diagnosis depends on electrocardiography Since most of these cases have no associated heart failure, treatment is limited to the use of ether-oxygen anesthesia and careful observation

Auricular Fibrillation—An irregular regularity of rate with a pulse deficit speaks for auricular fibrillation Unless associated with decompensation it does not ordinarily require stringent measures The following may be considered (1) ether-oxygen anesthesia, (2) procaine intravenously, 3 to 7 cc of a 1 per cent solution, (3) dicumarol to prevent postoperative pulmonary embolus if quinidine is to be used therapeutically [20]

Ventricular Fibrillation—This entity is usually sudden and fatal If one should be fortunate enough to suspect its onset from extrasystoles and thready tachycardia or else actually see it during intrathoracic surgery, then procaine is definitely indicated [21] Equally important, the surgeon and anesthetist should prepare for cardiac resuscitation

Acute Cardiac Failure—Left heart failure with pulmonary edema is the more frequent type to expect Signs and symptoms include low or normal pressure, weak rapid pulse, hyperpnea, cyanosis, and "wet respiration" with moist rales on auscultation

Treatment is as follows (1) oxygen under positive pressure with helium if available, (2) Cedilanid (a purified digitalis preparation), 4 cc intravenously, and repeat with 2 cc in one hour if necessary (Digitoxin, 4 cc, may be substituted), (3) caffeine, 7½ grains, intravenously, (4) rapid termination of surgery, and (5) if failure occurs during a continuous spinal anesthesia, one may contemplate an added dose to minimize right heart return [7,11]

Fibrillation During Thyroidectomy—The signs are as described above but usually are preceded by tachycardia and hypertension

Treatment consists of oxygen, Gynergin 0 5 to 1 0 mg intravenously, Lugol's solution, 40 to 60 drops in 500 cc of saline, and barbiturates (Pentothal-nitrous oxide anesthesia may be substituted for cyclopropane or ether)

Summary

An attempt has been made to consolidate and review the common cardiac and circulatory emergencies that may arise during anesthesia Treatment of these accidents as an integral part of the anesthetist's functions has also been outlined Discussion could probably be advanced about some specific therapeutic agents mentioned This, however, is not the most important aspect of the subject Fundamentally, one goal is of prime significance, and that has to do with the thought that every anesthetist should, first of all, familiarize himself with the accidents that may occur and, in addition, formulate a plan of approach to their treatment so that precious time will not be lost

Discussion

John H Geckler, M D, *Buffalo*—This paper, I think, has accomplished its purpose here—it has freshened our knowledge of cardiovascular emergencies and the accepted means of combating them Fortunately, most of us see very few of the more serious of these phenomena, but the danger is that we might get the idea that it can't happen to us and neglect to plan for possible use, unhoped for as it may be, of a quickly available method of treatment

I can add nothing to what has been said about choice of anesthesia However, once the choice has been made, it is wise not to be afraid to change it if the patient doesn't handle well I am sure most of us at some time or other have been amazed at how well the patient may do on what we didn't consider at first the anesthetic of choice

When I was a resident, these arrhythmias with cyclopropane, which were just classified as nonacute states, did not worry me I believed with Guedel that they were present in a certain plane,

and either lightening or deepening the anesthesia would abolish them [a] There were just two instances where relaxation was needed, and yet I thought it inadvisable to push the cycle till the arrhythmia disappeared But, for several years now, I have had a rather prominent "yellow streak" connecting my dorsal vertebral spines I resort only to the more conservative measures that have been mentioned (adding or changing to ether or perhaps the use of procaine) It is not that I believe the theory of hypothalamic hyperactivity is not sound, I am just no longer stubborn enough to try to prove it at someone else's risk. Perhaps Dibenamine is going to prove to be the drug of choice to stop these and other arrhythmias A recent editorial in *Gastroenterology* by Dr Alvarez quite enthusiastically cites the work of a couple of good physiologists and calls it the best adrenolytic drug yet found [b] It might even be better in thyrotoxicosis than the ergotamine preparation that was mentioned

Vago-vagal and carotid sinus reflexes I do not see very often, although for a good while I used to anesthetize throats locally in the hope of avoiding the former during intubation

I recall one hypertensive case during a total gastrectomy that responded to nothing, and it later developed that one of the units of blood I gave was mismatched I have been unable to determine for sure, since, whether it could have been the cause

ECTOPIC PREGNANCY WITH A STUDY OF AN ASSOCIATED CLINICAL SYNDROME

HAROLD C INGRAHAM, M D , MILTON M GARDNER, M D , and LEONARD E WITKIN, M D , New York City

(*From the Obstetrical and Gynecological Service of Lincoln Hospital*)

THE diagnosis of ectopic pregnancy is an unexpected or an exclusion diagnosis in the average hospital throughout the country At this hospital it is a common disease and because of its frequency certain aspects of history-taking, physical examination, diagnostic aids, and laboratory procedures assume paramount consideration in making the diagnosis

In the two-year period from January, 1945, to December, 1946, there were 80 ectopic pregnancies out of 1,929 admissions to the gynecological service Of the 1 929 gynecologic admissions there were 825 abortions of all types On the obstetrical service there were 3,219 completed deliveries for the same two-year period, making a total of 4,134 pregnancies treated at this hospital One out of 24 1 gynecologic admissions was an ectopic pregnancy, while one out of 51 6 pregnancies admitted to this institution was proved to be an ectopic pregnancy Wynne found a 1 3 per cent ectopic rate at Johns Hopkins Hospital [1] Counsellor recorded 2 24 per cent at the Jefferson Hospital [2] We found a 1 9 per cent ectopic rate in relation to the number of pregnancies admitted During this period there were 386 major surgical gynecologic operations One out of 4 9 cases proved to be an ectopic pregnancy

The frequency of pelvic inflammatory disease due to abortal, postabortal, and acute infections is very high in this area Is our ectopic rate related to this fact? Is there a definite clinical picture associated with the site of implantation? Are there any findings that appear frequently enough to be used to increase the range of diagnosis? This study aimed to answer these three questions

Material

The average age of this group was thirty years, with the distribution of cases equally divided between the third and fourth decade of life The percentage of single women was significantly high Eleven per cent of the patients were married, thereby confusing the idea of the pregnancy status of the patient This throws the burden of proof of pregnancy, a rather touchy problem, on the diagnostic acumen of the physician There were 210 previous pregnancies in this series of cases prior to the ectopic gestation One hundred fourteen, or 55 per cent, of these ended in abortions of some type This far exceeds the abortion rate described by the Ministry of Health of England which places it at 16 7 per cent, and the New York University Clinic which reaches 27 3 per cent [3 4] This potential exposure to infection and subsequent pathologic change in the pelvis was frequent in this series In addition to the numerous abortions the past history revealed additional precursors of pelvic changes (Table 1)

TABLE 1 —HISTORY OF LOWER ABDOMINAL DISEASE

	Percentage
History of pelvic inflammation	26 2
Previous ectopic history	5 0
Previous appendectomies	5 0
Previous gynecologic operations	6 2

Present History —This series falls into two clinical categories The larger group is called manifest ectopic pregnancies and is composed of cases which are diagnosed promptly or are urgent laparotomies within twenty-four hours of admission The smaller group is nonurgent cases which require longer periods of study before they are properly diagnosed or an exploratory laparotomy is done These are called latent ectopic pregnancies In this series there were 53, or 66 2 per cent manifest and 27, or 33 8 per cent latent ectopic pregnancies

The lapse of time from onset of pain to operation in ectopic pregnancies was fairly characteristic of both manifest and latent

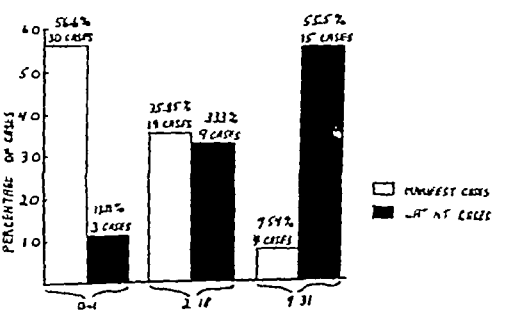

FIG 1 Duration of bleeding to operation (days)

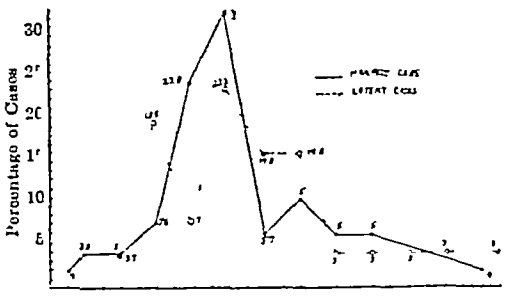

FIG 2 Duration of time from date of last menses to operation (weeks)

cases Forty-two, or 77 7 per cent, of the manifest cases had pain under five days Of these, 30, or 56 6 per cent, had an acute onset of pain under twenty-four hours Only three, or 11 1 per cent, of the latent cases had pain under five days The remainder of the latent cases had longer histories of pain, making their diagnosis more confusing

The duration of bleeding to operation is illustrated in Fig 1 The manifest cases had early histories of bleeding as compared to the latent cases A large group of the manifest cases had no bleeding at all

Figure 2 points out that the period of time from the last menstrual period to the time of operation in both manifest and latent ectopic pregnancies falls within eight to twelve weeks

In routine history-taking the symptoms of shoulder pain, fainting, or passage of tissue were variably elicited These symptoms were found significantly in the manifest cases Thirty-nine per cent of the manifests had shoulder pain, while 3 7 per cent of the latents presented this symptom Fifty-one and three-tenths per cent of the manifest cases fainted or felt faint This was not present in any of the latent cases Although only one manifest case passed tissue there were 14 8 per cent of the latents who did

TABLE 2 —BLEEDING MANIFESTATIONS

Type	Manifest (Per Cent)	Latent (Per Cent)
Spotting	32 1	40 9
Bleeding	26 3	22 4
Clots	13 2	26 2
None	28 4	10 5

H B Atlee in a survey of 100 cases showed that 27 3 per cent of the "acute" and 4 5 per cent of the "chronic" ectopic pregnancies had no bleeding [5] His series closely parallels this study as revealed in Table 2 where there were 28 4 and 10 5 per cent in the manifest and latent cases, respectively A study of Table 2 shows that no type of bleeding was common to either manifest or latent groups

Physical Findings —Twenty-three, or 40 3 per cent, of the manifest cases and 2, or 7 4 per cent, of the latent cases had the typical appearance of a patient in shock This picture of shock was more apparent when the pulse and blood pressure were recorded It was found that 23, or 47 1 per cent, had a systolic pressure under 90 mm Hg, and 25, or 47 1 per cent, had pulse rates over 100 This was seen only in the manifest cases All latents had normal blood pressures and slow pulses The temperature of the manifest cases in 15 2 per cent was under 98 F This was not present in the latent cases Ten cases, or 19 per cent, of the manifest cases had temperatures recorded over 100 F A larger percentage, 33 3 per cent, of the latents revealed this elevated temperature

TABLE 3 —ABDOMINAL EXAMINATION

Sign	Manifest (Per Cent)	Number of Cases	Latent (Per Cent)	Number of Cases
Distention	26 6	14	14 8	4
Mass	9 5	5	25 9	7
Spasticity	24 7	13	14 8	4
Tenderness	96 6	51	70 3	19
Bilateral	34 7	18	22 2	6
Unilateral	62 7	33	48 1	13
Rebound	64 6	34	25 9	7
Bilateral	32 3	17	11 1	3
Unilateral	32 3	17	14 8	4

Abdominal examination in ectopic pregnancies caused tenderness and rebound pain fairly persistently, but tenderness was significantly high in both groups Both the manifest with 62 7 per cent unilateral tenderness and 48 1 per cent of the latent cases illustrated this fact (Table 3) All of the other signs appeared inconsistently and can readily be present in other abominal conditions

TABLE 4.—VAGINAL EXAMINATION

Sign	Manifest (Per Cent)	Number of Cases	Latent (Per Cent)	Number of Cases
Tender on motion of cervix	66 5	35	40 7	11
Uterus larger than normal	45 6	25	48 4	13
Adnexal masses or tenderness	85 5	45	77 7	21
Bilateral	19 0	10	18 5	5
Unilateral	66 5	35	59 2	16
Bulge or tenderness in cul de-sac	47 5	25	44 4	12

Vaginal examination in ectopic pregnancy revealed many positive findings (Table 4) It was apparent that bilateral adnexal masses or bilateral tenderness occur infrequently The findings of tenderness on rocking the cervix, a slightly enlarged uterus, a unilateral

adnexal mass or tenderness, and a cul-de-sac bulge or tenderness were persistent in the largest percentage of the patients

Laboratory Findings—Thirty-three of the manifest ectopic pregnancies had no erythrocyte sedimentation rate (E S R) tests done Of the remainder, 11 had E S R 's over thirty, which in this hospital is considered elevated In the latent cases 12 had high E S R 's rates (i e , over 30) The impression gained is that in either type of case the E S R is a nonspecific test

The hemoglobin, however, gives a better lead as to the diagnosis Sixty per cent or below was considered the critical level Twenty-three, or 40 4 per cent, of the cases of manifest ectopics had findings under 60 per cent An additional five had no hemoglobin test performed because of the urgency of the case Four (14 8 per cent) of the latents also had a low hemoglobin It is felt that hemoglobin determinations elicit a most dependable laboratory finding in the manifest cases and is of questionable value in latent cases

Preoperative Diagnosis and Diagnostic Aids—The preoperative diagnosis in the manifest cases was correctly made in 90 5 per cent of the series There were five missed diagnoses A colpotomy performed as a diagnostic aid was used to establish a presumptive ectopic pregnancy in one of these cases The other four were operated on for other surgical emergencies One was wrongly called a twisted ovarian cyst, another a strangulated umbilical hernia, and two were thought to be acute appendicitis

A considerable amount of thought for a positive diagnosis was required in the latent cases Ectopic pregnancy was diagnosed outright in four cases Another four cases were suspected One was proved by a positive Friedman test for pregnancy, another had a curettage and returned for a subsequent colpotomy, and, because blood was found, a laparotomy was done The other two were explored on the suspicion of ectopic gestation

Ten latent cases had a Friedman test, a curettage, or a colpotomy done to establish a diagnosis Colpotomy proved the diagnosis three times Eight curettages were performed and aided in each case in proving the presence of an ectopic Five Friedman tests were performed, and, because four were positive, a diagnosis of ectopic pregnancy was declared present The other was negative but still required an exploratory laparotomy

Five patients went into collapse after a period of time, either as a result of examination or from a continuation of the pathologic process while waiting for a laboratory report to be returned

Seven patients were diagnosed wrongly, and the actual conditions were only revealed at operation The errors of diagnosis are only interesting in that almost every gynecologic disease can simulate an ectopic pregnancy by history, physical examination, or laboratory procedure Table 5 illustrates this fact, since the following diagnoses were made in the latent cases as the initial diagnosis

TABLE 5.—MISTAKEN DIAGNOSIS

Diagnosis	Number of Cases
Fibromyomata uteri	2
Threatened abortion	4
Incomplete abortion	5
Pelvic abscess	2
Pelvic inflammatory disease	5
Ovarian cyst	5
Acute appendicitis	2
Gynecologic observation	1
Second degree retroversion of uterus and prolapsed ovary	1

Operative Findings—Forty-four cases (42 5 per cent) of the 80 in the series evidenced salpingitis pathologically or by findings at operation Seven cases, or 8 8 per cent, had salpingectomies prior to the present ectopic gestation Fifty-one and three-tenths per cent had proved salpingitis or salpingectomies This is a significant number when viewed as a causative agent in considering ectopic pregnancy

TABLE 6.—SITE OF PATHOLOGY

Site	Manifest (Per Cent)	Number of Cases	Latent (Per Cent)	Number of Cases
Tubal abortion	20 8	11	74 4	20
Ampular rupture	26 3	14	25 6	7
Isthmic rupture	18 9	10		
Fimbrial rupture	11 3	6		
Interstitial rupture	15 2	8		
Not specified	7 5	4		

The large percentage of cases with tubal abortion certainly indicated where the difficulty in diagnosis arose (Table 6) The moderate reaction by the patient to the pathology paralleled her mild symptomatology The acute rupture did not always give the picture of ectopic pregnancy as shown by the behavior of those that ruptured in the latent group

Our attempt to associate certain clinical pictures with the site of the pathology and its eventual course were significant in the tubal abortion and interstitial pregnancy Tubal abortions were more prone to be of the latent type in the expression of its diagnosis and were more apt to be missed It was only in a *post hoc* re-evaluation that its presence assumed importance as a surgical disease Its clinical

and laboratory findings will always confuse the practitioner The interstitial ruptures, however, illustrated a definite picture almost attaining the characteristics of a clinical syndrome The common history of fainting, acute onset of pain, absence of vaginal bleeding, intense shock, low blood pressure, rapid pulse, low hemoglobin, abdominal tenderness that tended to be bilateral, and unilateral mass are outlined in the following cases These cases revealed syndromatic symptoms and were considered interstitial pregnancies because of the site of rupture as viewed by the surgeon or the pathologist

Case Reports

Case 1 —A thirty-two-year-old gravida VII, Para 4, was admitted in shock with finding of intraperitoneal bleeding There was bilateral abdominal tenderness, and a unilateral mass was felt The operator reported an interstitial rupture, but the pathologist makes no mention of its location

Case 2 —The patient, a twenty-three-year-old gravida III, Para 2, had been treated as a threatened abortion of a five-month gestation on a prior admission On her present admission she gave a history of developing shock symptoms following intercourse Physical findings were typical of intraperitoneal bleeding plus bilateral tenderness, a unilateral pelvic mass, and a large uterus. The surgeon and the pathologist both reported a definite interstitial pregnancy with invasion of myometrium by syncystial masses and linings of decidua and chorionic villi

Case 3 —A twenty-six-year-old gravida II, Para 1 had a history and findings pointing to a ruptured ectopic pregnancy There was tenderness over whole of abdomen and a unilateral mass in the pelvis but no external bleeding The operator reported an interstitial rupture The pathologist found endometrium in the site of rupture

Case 4 —This was a twenty-five-year-old gravida I, Para 0, with a four-month amenorrhea She was admitted in shock with no vaginal bleeding Physical findings were typical of interstitial pregnancy The operator reported the entire top of the right side of the uterus was blown off The pathologist corroborated the findings

Case 5 —The patient was a twenty-nine-year-old gravida I, Para 2, with a typical history of intraperitoneal bleeding and ruptured ectopic pregnancy Her period of amenorrhea was three months, and the uterus was enlarged to a three-month gestation The surgeon and pathologist concurred that the location of the ectopic pregnancy was interstitial.

Case 6 —This patient was a twenty-nine-year-old gravida III Para 1, with a typical history and findings of ectopic pregnancy without vaginal bleeding Only the operator felt this was an interstitial pregnancy The pathologist could not place the location because of the disruption of the surrounding tissue

Case 7 —A twenty-one-year-old gravida II, Para 1, was admitted actually ill without a history of vaginal bleeding Physical examination revealed findings of a possible ectopic pregnancy The operator and pathologist reported an interstitial rupture in an early ectopic pregnancy

Case 8 —This was a thirty-one-year-old gravida II, Para 1, admitted with a typical history of ectopic pregnancy There was no vaginal bleeding, and the patient was in acute shock. The operator noted an early ruptured interstitial pregnancy The pathologist made no reference to the site of rupture

Summary

1 Eighty cases of ectopic pregnancy are reviewed

2 The history, physical findings, and laboratory findings are discussed

3 The association between lower abdominal disease and ectopic pregnancy was found to be significantly high

4 A clinical picture associated with the site of implantation is evaluated

LINCOLN ON PRIVATE PROPERTY

Property is the fruit of labor property is desirable, is a positive good in the world. That some should be rich shows that others may become rich, and hence is just encouragement to industry and enterprise Let not him who is houseless pull down the house of another, but let him labor diligently to build one for himself, thus by example assuring that his own shall be safe from violence

I take it that it is best for all to leave each man free to acquire property as fast as he can Some will get wealthy I don't believe in a law to prevent a man from getting rich, it would do more harm than good.

SUBCUTANEOUS CYSTS OF RHEUMATOID ARTHRITIS

PHILIP L STAUB, M D , Staten Island, New York

(From the Orthopedic Service of the Halloran Veterans Administration Hospital)

PATIENTS with rheumatoid arthritis occasionally develop associated subcutaneous cystic masses Because of their close resemblance to bursae or ganglia, these cysts may easily be mistaken for separate clinical entities, but they are essentially part of the picture of rheumatoid arthritis

In the case to be reported the patient had many subcutaneous cystic lesions, some of which simulated olecranon bursae or wrist ganglia The diagnosis of these cysts was the subject of considerable speculation and dispute, but microscopically they showed the synovial changes typical of rheumatoid arthritis

Case Reports

The patient was a forty-two-year-old white man who first noticed aching pains in his feet in August, 1940, about seven years prior to his latest hospital admission During the next nine months his ankles, knees, hips, shoulder, elbows, wrists, and fingers gradually became painful and swollen From April, 1941, until August, 1942, he was given gold injections at another hospital and he slowly improved Although he was rejected by the Army in January, 1942, because of his joint involvement, pain and swelling had completely subsided before the completion of the gold therapy, and in November, 1942, he was able to pass a physical examination for induction into the Army

The patient was asymptomatic until March, 1943, when he noted a small, soft nodule over the medial aspect of the head of the right first metatarsal bone Because of the nodule's tenderness the patient was hospitalized Shortly thereafter his various joints again became painful and swollen Additional tender subcutaneous nodules appeared on the plantar surfaces of his feet, and a fluctuant, tender, cystic mass appeared over each olecranon He subsequently received a medical discharge from the Army

Subcutaneous nodules and cysts continued to appear on the forearms, wrists, and feet, and because of their tenderness the patient was admitted to Halloran Hospital for treatment

Examination was essentially negative except for somewhat symmetric, tender, subcutaneous cystic masses about the olecranon processes and on the dorsal surfaces of both forearms and wrists (Fig 1) These varied in size from 0 8 to 6 4 cm. in diameter Several firm, cystic, solid, tender masses were palpable on the plantar surfaces of the forefeet and the great toes (Fig 2)

There was no swelling or restriction of motion of any joints, and the skin about the joints showed no trophic changes

X-rays of the hands and feet showed numerous,

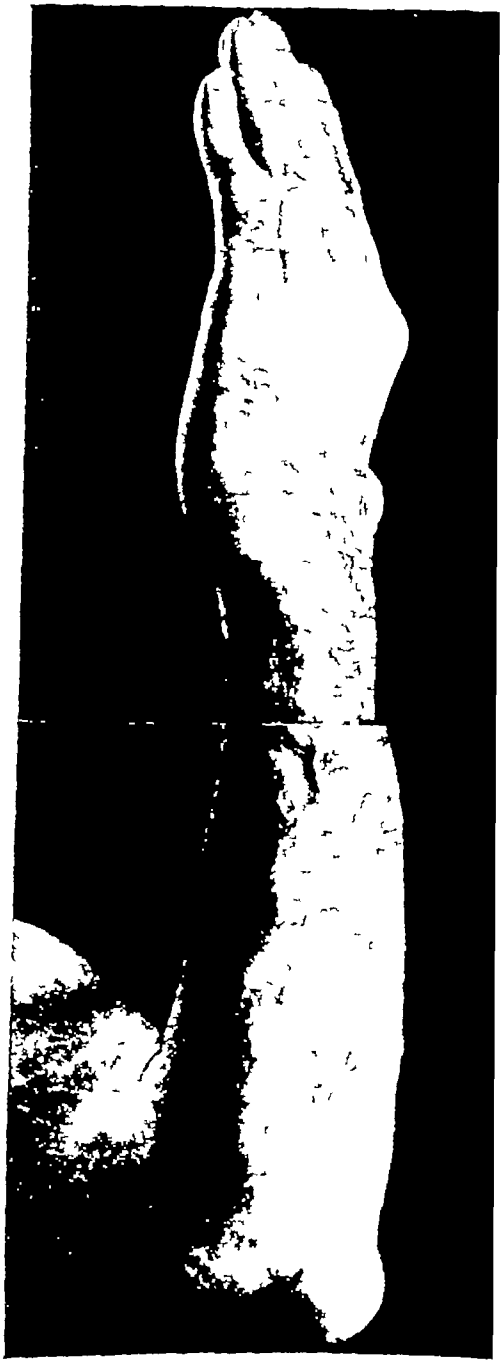

FIG 1 Subcutaneous cysts on left elbow, forearm and wrist.

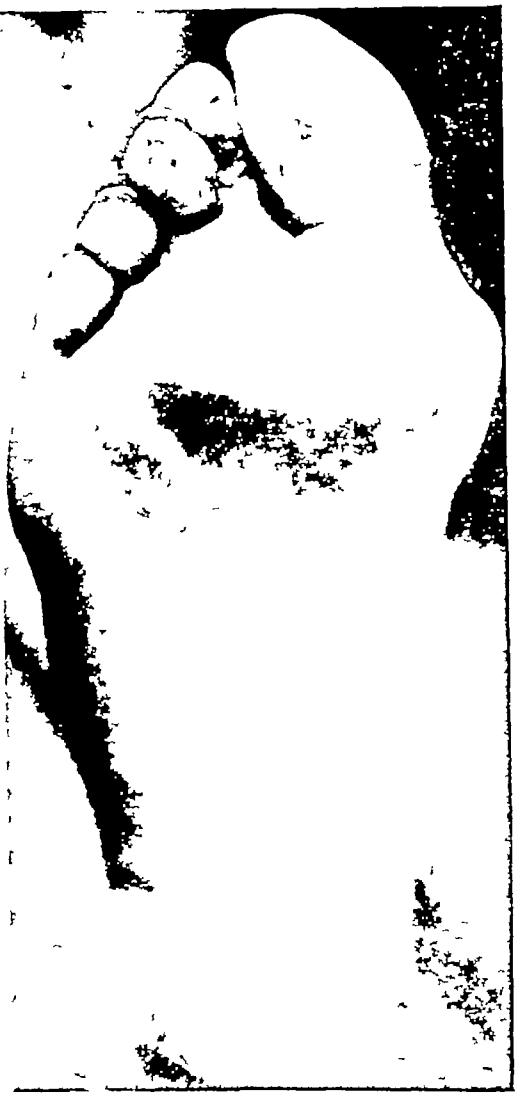

FIG 2 Subcutaneous lesions beneath the heads of the first and third metatarsal bones, right foot

punched-out, small cystic areas of rarefaction in the small bones of the carpus and of the digits Minimal hypertrophic changes were seen in the elbows There was no atrophy of bone so characteristic of rheumatoid arthritis

Laboratory studies were as follows white blood cells 9,500, polymorphonuclear neutrophils 67 per cent, lymphocytes 25 per cent, eosinophils 4 per cent, red blood cells 4,950,000, hemoglobin 15 4 Gm., sedimentation rate (Wintrobe) 30 mm uric acid 3 4 mg per cent, cholesterol 310 mg per cent, calcium 9 6 mg per cent, and alkaline phosphatase 2 5 units

All of the tender masses were excised with considerable amelioration of symptoms The cysts

FIG 3 Section through a subcutaneous cyst showing a central area of necrosis—(A) with cystic spaces, (B) with hyalinized collagenous tissue, and (C) surrounded by palisaded epithelioid cells (60×)

about the elbows and forearms contained watery, amber-colored fluid Those in the wrists involved tendons and sheaths and were filled with gelatinous, orange-colored material The tendinous tissue was in a state of deterioration varying from moderate thickening to complete degeneration and necrosis The masses in the front were firmer and more solid than elsewhere, with only slight liquefaction but with similar affection of the tendons and their sheaths

Microscopic examination of all of the lesions was essentially that of the soft tissue changes of rheumatoid arthritis Because of the collapse of the cyst walls, the cavities were not well demonstrated microscopically The synovial membranes were thickened by hyaline connective tissue fibers In the central portion of each lesion was a diffuse, pink, granular area of necrosis containing cellular debris and lymphocytes About this was an area of dense, partially hyalinized, collagenous tissue, containing a number of dilated capillaries surrounded by collections of fibroblasts, histiocytes, lymphocytes, and plasma cells Beyond was seen an area of palisaded epithelioid cells (Fig 3)

An examination of the patient six months after surgery revealed that, while his general arthritic picture was unchanged, he was completely relieved of the symptoms of those rheumatoid lesions which had been excised However, several new moderately tender lesions had since appeared on the plantar and dorsal surfaces of the right foot Other masses may be expected to develop from time to time, and their complete removal will probably alleviate the symptoms

Comment

A search through the medical literature fails to reveal much concerning these cystic lesions of rheumatoid arthritis It is probable that these fluctuant masses developed from solid subcutaneous nodules which are so often observed in this disease These nodules have a characteristic central area of necrosis, and, if liquefaction ensues, a cystic lesion results Bennett *et al* state that the nodule of rheumatoid arthritis has a zone of central necrosis which in well-developed lesions undergoes liquefaction and forms bursa-like cavities [1] These cavities are lined with a regular palisading arrangement of cells which is a prominent feature of this lesion

Weber has reported enlarged synovial bursae with thickened walls and ganglia of the hands and wrists In describing these masses in three patients, he says that they were solid rather than cystic with necrotic, gelatinous central areas [2]

Summary

A case of rheumatoid arthritis with many tender subcutaneous cystic lesions is reported Although these cysts simulate bursae and ganglia, they are part of the systemic picture of rheumatoid arthritis Tenderness disappeared after the excision of these masses

"DR JONES" SAYS—

Thirty-odd years ago a country doctor (a good one) told me his own story—the only true one I ever heard where any good came out of a cancer patient being treated by a quack He'd quit school when he was in high school and taken up carpentry He was married and had a teen-age daughter His wife developed cancer but the doctor she went to didn't make a diagnosis 'til it was well advanced Then someone told them about a "doctor" that advertised to cure cancer and they went to see him. He said he could cure it, "treated" her 'til their money was gone, then washed his hands of the case She died, of course

"I decided, then and there," he told me, "I'd be a doctor myself and an honest one" He went back to school, in the class with his daughter, graduated, and, four years later, came out of Syracuse Medical College with his M D He practiced for years in a village out by Cortland County way, and, if I'm not mistaken, his son's practicing there now

What reminded me of that story was a report published a while ago by the A M A Council on Pharmacy and Chemistry People with cancer and others that haven't got it but fear it, it said, are still being victimized by the sale of quack remedies What's more, some of these outfits even advertise to physicians and mislead some of 'em with their plausible sounding claims The report listed several "Collodaurum," supposed to be a gold cure, iodine preparations called "Iriodine" and "Radiodine", Doch's synthetic antitoxins, Hett "Cancer Serum", "AF-2" and others

The thing the Council stresses is that, while research is turning up interesting drug possibilities, it's all experimental and no drug cure has yet been found Up to now the only established treatments are surgical or with irradiation X-rays, radium and so on In the meantime, in a recent study of the doctors in important medical specialties, surgeons have the lowest cancer death rate They evidently practice what they preach early diagnosis and prompt treatment—*Paul M Brooks, M D*

THE ADMINISTRATION OF CURARE BY ELECTROPHORESIS

Preliminary Report

E Neuwirth, M D , New York City

(From the Department of Physical Medicine, Mount Sinai Hospital, and the Arthritis Clinic, St Luke's Hospital)

THE ability of curare to relieve muscular spasm induced the author to administer it locally by electrophoresis (iontophoresis) in a number of conditions where a muscle or a group of muscles were in a state of painful spasm

The clinical use of curare is dependent upon its property to create a transient interruption in neuromuscular transmission at the myoneural junction The myoneural block may be total or partial In this study curare was used in the form of "Intocostrin," which is an aqueous extract of purified curare *

The effect of curare when injected intravenously or intramuscularly is evanescent and is often associated with unpleasant reactions In an effort to avoid the uncomfortable systemic reactions incident to the parenteral administration of curare and at the same time bring about an intense local effect, the author introduced curare into the tissues by electrophoresis There is evidence that the introduction of certain drugs into the body by means of the galvanic current increases their pharmacodynamic effects, and improves the therapeutic results [1] The author used Bourguignon's technic of electrophoresis which is based on ion localization [2]

Theory of Ion Localization

From experimental studies with electrophoresis Bourguignon showed that chemical substances may be deposited along the path of the current determined by the position of the electrodes [2] He further demonstrated that ions are not only driven into the blood stream but that they are also removed from the circulation and are anchored along the route of the current Leduc, on the other hand, considered it impossible to localize ions within specific tissues [3] He felt that the galvanic current transports therapeutic substances beyond the epidermal barrier into the capillaries where they are carried away by the blood stream.

In order to deposit therapeutic substances at a desired site, it is necessary to route the current across the part to be treated and to cause as little diffusion as possible To achieve this objective, small electrodes are employed and applied circumspectly to judiciously selected points of entry and exit of the galvanic current, at the opposite sides of a lesion A current of low intensity is employed, and the treatment continued for from twenty-five to thirty minutes Bourguignon demonstrated, by means of oscillometry, that in transcerebral electrophoresis the peak effect of ion transfer occurs after twenty to twenty-five minutes of current flow [2] To obtain maximum benefit from the administration of curare, a correct diagnosis is essential This enables proper placement of the electrodes Too often the area of pain is treated instead of the source of pain

Leduc used large electrodes and strong electric currents [3] This was done in accordance with his belief that electrophoresis represented an intravenous injection without the needle prick His objective was to introduce large amounts of drugs into the body With this technic the position of the electrodes is immaterial The "active" electrode covers not only the area to be treated but also much of the surrounding tissue The "dispersive" electrode is at least twice as large as the therapeutic electrode After soaking in ordinary hot tap water, the dispersive electrode is placed anywhere on the cutaneous surface Leduc's old "ionization" technic is still popular in the United States

Technic of Application

Since curare is an alkaloid and carries a positive electric charge, the polarity of the electrode must be positive The electrode, which is cut to the dimensions of the lesion to be treated, is completely saturated with Intocostrin and is applied to the skin over the lesion The cathodal electrode is of the same size or somewhat larger It is thoroughly soaked in hot tap water, wrung out, and then applied to the opposite side of the lesion The electrodes employed by the author consisted of fine pore cellulose sponge (E I du Pont de Nemours) covered on one side with smaller metal foils

After the electrodes are connected to the proper terminals of the galvanic generator, and after all meters and controls are properly set, the current is turned on and its intensity is gradually increased A sensation of pricking is all that the patient is supposed to experience

At the end of thirty minutes, the intensity of the current is gradually reduced, and, finally, the current is turned off After removing the elec-

* Intocostrin was generously supplied by E R. Squibb & Sons.

trodes, the treated area is dried and covered with a soothing lotion (e g , Johnson's Baby Lotion) Treatments are given three times weekly The area of the skin to which curare is applied generally shows cutaneous vasodilatation The part feels warm and the temperature of the skin is increased

Conditions Treated

Electrophoresis of curare relieves muscular spasm, reduces local and referred pain, alleviates tenderness, ameliorates stiffness and rigidity, and increases motion

The degree of relief brought about by curare varies, it depends upon individual response and pathologic process In no case have any adverse general effects been noted during or following the administration of curare by electrophoresis

Intocostrin was employed in conditions which previously failed to respond to other therapeutic measures This preliminary report is based upon 31 patients who were treated with 257 applications of curare Eighteen of the patients were women, and 13 were men Their ages ranged from twenty-three to sixty-four years

The following conditions were treated

Facial Contracture —Curare was administered by electrophoresis to four patients in whom facial contracture developed in the wake of Bell's palsy Considerable diminution in the degree of the contracture occurred in these patients A case of facial tic was treated in the same way In this patient, a man of forty-two years, vestiges of a facial palsy of the left side were still discernible The improvement noted after eleven treatments was striking

Fibrositis —Ten cases with tender palpable "fibrositic" nodules responded symptomatically to the application of curare by electrophoresis The nodules were present in the muscles of the neck, the shoulder, and pelvic girdles In two instances where post-traumatic scar tissue caused painful muscular spasm, complete relief of pain resulted from the use of curare *

Acute Low Back Pain —One patient, a man aged fifty years, was stricken with an attack of acute pain in the lower back after lifting a heavy bag of flour In this case, curare was applied to the lumbosacral region with excellent symptomatic relief

A lesion of the fifth intervertebral disk was responsible for another case of acute low back pain which was aggravated by movement, coughing, or straining Curare relieved the pain considerably This treatment was supplemented with other measures, including fracture boards, rest, and heat

Lesions of the Vertebral Column —Two patients with pain in the neck due to osteoarthritis of the cervical spine were treated with curare The drug was applied to the posterior aspect of the neck, greatly relieving the painful muscle spasm

In two other patients with osteoarthritis of the lumbar spine, curare was introduced into the tissues of the involved region while the negative electrode was placed over Scarpa's triangle. Gratifying relief of muscular spasm and pain was obtained

In two women with pain in the neck, x-ray examination disclosed the presence of old fractures of the cervical spine These patients responded to curare Pain and muscle spasm were relieved, and mobility of the cervical spine was increased

Chronic Arthritis —Two women and one man with osteoarthritis of the knee joints responded better to curare than two other women with rheumatoid arthritis of the wrists The small number of cases does not allow definite conclusions as to the value of curare in chronic arthritis

Traumatic Arthritis —In one case of subacute traumatic arthritis of the right ankle the pain was diminished and the mobility increased after four treatments with curare

Summary

1 A preliminary report is presented on the local use and therapeutic action of curare administered by electrophoresis

2 Curare was administered to 31 patients suffering from various ailments including facial contracture, fibrositis, neck and low back pain, and chronic arthritis of the spine and peripheral joints

3 Electrophoresis has been performed according to the method advocated by Bourguignon The essential features of this technic are small electrodes, low intensity galvanic current, and transverse position of the electrodes

4 The therapeutic results were gratifying but not uniform No unpleasant systemic reactions were observed

*One should be aware of the fact that areas of spasm associated with pain and tenderness in the muscles of the neck, shoulder girdle or back may be symptoms of spinal nerve root involvement Fibrositic deposits are not infrequently confused with fat lobules which herniated through their fibrous investing membrane.[4] Such fibrofatty tissue structures may cause painful spasm in neighboring muscles

TORSION OF THE OMENTUM

WALTER J PUDERBACH, M D , Brooklyn, New York

(From the Lutheran and Swedish Hospitals)

THE discovery of blood or blood-stained fluid in the abdomen in the course of operations for acute surgical emergencies, especially those diagnosed preoperatively as acute appendicitis, should direct the surgeon's attention to the possibility of an existing omental torsion This condition as one of the causes of intra-abdominal bleeding is not sufficiently stressed in the literature, and, unless special pains are taken to examine the omentum, may not be recognized at operation

Torsion of the omentum is a condition almost never diagnosed correctly preoperatively, notwithstanding the fact that the majority of cases have been reported by experienced surgeons About 400 cases have been listed in the world literature to date, but undoubtedly this syndrome presents itself much more frequently than is recorded [1-8]

In four out of five cases the preoperative diagnosis is acute appendicitis, since the symptom complex is usually localized about the right lower quadrant of the abdomen However, omental torsion may simulate almost any other acute surgical condition, such as perforated peptic ulcer, pancreatitis, acute cholecystitis, or strangulated hernia

The signs and symptoms in general are those of an "acute surgical abdomen" Often, however, they may not be quite so pronounced as those of the more common surgical emergencies, so that there may be a delay of from twenty-four to forty-eight hours before surgical intervention appears mandatory A variety of differential features, such as palpation of an abdominal mass, paucity of vomiting, relief of symptoms in the prone position, etc , have been stressed by a number of authors However, these patients usually are moderately obese so that any mass present, especially if not of great size, is either difficult or impossible to palpate through the abdominal wall Furthermore, the various points of differential diagnosis that have been enumerated are usually too vague to be of practical value to the operating surgeon At any rate, whether diagnosed correctly preoperatively or not, torsion of the omentum is a surgical emergency and requires prompt operative intervention

Types

Torsion of the omentum may be complete or incomplete and either acute or recurrent

Two types of omental torsion are found

1 *Primary torsion*, due to no definitely known cause, is usually found in the obese individual A plausible theory is that the heavy, fat-laden omentum may rotate about the larger vessels in its substance which are acting as a pedicle, similar to the maneuver which results in a twisted ovarian cyst A history of sudden trauma or unusual exertion which is said to initiate this twisting motion is not often elicited, and a correct preoperative diagnosis is a great rarity

2 Secondary torsion is due to twisting of the omentum about its axis when its distal end is anchored by adhesions to an abdominal operative scar, neoplastic or inflammatory intra-abdominal pathology, or a hernial sac The last type, simulating a strangulated hernia, is relatively common and should be the one most amenable to a correct preoperative diagnosis

All or only a portion of the omentum may be involved The amount of blood found in the abdomen at operation depends, of course, upon the degree to which the torsion has embarrassed the vascular supply of the involved omentum If torsion is incomplete and of short duration, only edema and congestion may be present If complete, strangulation occurs First, there is occlusion of the omental veins, followed by thrombosis, then hemorrhage through ruptured capillaries If it is unrelieved, arterial occlusion and necrosis of the affected omentum follows

Resection of the involved omental mass is sufficient to effect a cure and is strongly advisable, in order to prevent a recurrence, even if the omentum is still viable

Recurrent torsion of the omentum is a definite entity If exploration is carried out because of recurrent attacks of abdominal pain, a thorough inspection of the great omentum should never be omitted Induration or healed infarction of a portion of the omentum may be evidence of spontaneous subsidence of an omental torsion

Mortality rates have dropped steadily, mainly because of earlier operative intervention Earlier reports of ten to fifteen years ago listed a mortality of 15 per cent A British report from 1945 recorded an operative mortality of 5½ per cent [4] Certainly, with prompt surgery there should be little or no mortality in this condition

Three previously unreported cases are presented in abstract as illustrative of the symptom complex that may be present

Case Reports

Primary Torsion of the Omentum

Case 1—E S, an obese, eight-year-old white girl, was admitted to the hospital with a history of right lower quadrant pain of twenty-four hours duration The pain was stated to radiate from McBurney's point to the back and along the medial aspect of the right thigh. The patient was nauseous but had not vomited There was a history of constipation of long duration Temperature was 101 F A leukocytosis of 17,900 white blood cells with 79 per cent polymorphonuclears, 16 stab forms was present

Abdominal examination revealed tenderness and muscle spasm localized only to the right lower quadrant, with slight rebound tenderness over McBurney's point Rectal examination was negative A diagnosis of acute appendicitis was made At operation a large quantity of bloody fluid was found in the abdomen The abdomen was explored and an egg-sized mass of omentum was found in the upper abdomen, unattached to any other organ This mass was partially necrotic and densely hemorrhagic Following resection, the patient made an uneventful recovery

Case 2—A. P, a forty-four-year-old white woman, was admitted with a history of upper abdominal pain of twenty-four hours duration Leukocytosis and a temperature of 101 F were present Because physical findings were not clear cut, it was decided to observe this patient for a short period. The pain increased in intensity and an exploration was decided upon Preoperative diagnosis was acute cholecystitis At laparotomy, a large quantity of blood-stained fluid was found The bleeding was observed to originate from a large hemorrhagic segment of omentum which was found to be in complete torsion about its long axis. The gallbladder was uninflamed but contained a number of calculi After resection of the infarcted omentum and cholecystectomy, the patient recovered uneventfully

Secondary Torsion of the Omentum

Case 3—J O'D, a forty-two-year-old white man, a confirmed alcoholic, was admitted with a story of generalized abdominal pain of six hours duration For the past ten years this patient had been treated for duodenal ulcer A laparotomy (gastrorrhaphy) for perforated duodenal ulcer had been performed four years previously For the past three months the patient had experienced recurrent attacks of severe upper abdominal pain and, because of his history, was treated for ulcer His present illness began six hours before admission with severe upper abdominal pain which soon became generalized over the entire abdomen There was no vomiting Leukocytosis was present A scout film of the abdomen was negative for pneumoperitoneum. The patient was in shock and his physical findings were those of a perforated peptic ulcer After suitable preparation, the abdomen was opened, and a considerable quantity of bloody fluid was found The entire large omentum was hemorrhagic. Its free edge was adherent to site of the old operative scar, and complete torsion with strangulation of the omentum had occurred Recovery followed resection of the great omentum

Summary

1 The presence of bloody fluid in the abdomen is an important finding in torsion of the great omentum This condition should be kept in mind in any acute surgical emergency when operative findings do not coincide with the preoperative diagnosis

2 When laparotomy is performed for recurrent, vague, abdominal pain, especially right lower quadrant pain, a thorough inspection of the great omentum should never be omitted

3 Torsion of the omentum may simulate any one of the more common surgical emergencies

4 Recurrent torsion and detorsion is a definite clinical entity and should be considered more frequently in differential diagnosis

STANDARDIZATION OF SURGICAL SUTURES

The Commodity Standards Division of the National Bureau of Standards has issued a series of recommendations for the types and sizes of surgical sutures, copies of which may be obtained by addressing the National Bureau of Standards at Washington 25, D C

Case Reports

THE BRENNER TUMOR

J IRVING KUSHNER, M D , F A C S , Bronx, New York

(*From the Department of Pathology and Medical Research of the Bronx Hospital*)

THE Brenner tumor is an unusual type of non-malignant epithelial ovarian neoplasm Orthmann first described it, classifying it as a fibroepithelioma [1] Brenner was the first observer to segregate it as a distinct entity and called it "oöphoroma folliculare "[2] Although its origin has not yet been definitely determined, the tumor probably arises from collections of indifferent epithelial cells—Walthard's cell nests—in the ovary [3 4] Microscopic cell nests, composed of cells resembling those composing the Brenner tumor, have repeatedly been found in the hilus of an otherwise normal ovary

These tumors are not accompanied by a distinctive clinical picture As a rule, unless they produce symptoms because of their size or situation, they are discovered only by accident As far as is known, they have no hormonal action They are benign, and they do not produce ascites and do not metastasize or recur [5]

We wish to report four cases occurring at the Bronx Hospital from 1932 to 1948, inclusive

Case Reports

Case 1 —A N , a fifty-two-year-old white housewife, was admitted on October 21, 1941, because of painless vaginal bleeding on several occasions during the past six months She was a gravida III, Para 2 Her menopause had occurred six years previous to this admission

Examination was essentially negative except for a large mass arising from the right adnexa reaching almost to the umbilicus

Through a left paramedian incision, a right salpingo-oöphorectomy and appendectomy were done under spinal anesthesia

The specimen received was a 22 cm by 17 cm cystic mass The surface was smooth and blush-pink in color On section, it was multilocular and was filled with a clear serous fluid One area showed a solid tumor mass 7 by 4 5 cm. in size, hard in consistency, and yellowish-white in color

Microscopically, section of the cyst wall revealed a papillary serous cystadenoma Sections of the solid mass forming part of the cyst wall showed solid and cystic masses of spindle-shaped or epithelial-like cells scattered in a rather sparse manner throughout a dense, hyalinized connective tissue stroma (Fig 1) In many areas these cell nests were grouped about a lumen Diagnosis was Brenner tumor of the ovary

The patient made an uneventful recovery and was discharged well on the twelfth postoperative day Follow-up studies in 1947 (six years after operation) reported the patient alive and well.

Case 2 —A forty-nine-year-old white woman was admitted on May 18, 1942, because of backache and urinary frequency of a year duration Menstrual periods began at age fourteen They were of the thirty-day type with a three-day flow Her last menstrual period was on May 10, 1942 She was a gravida V, Para 4

Examination revealed a normal-sized uterus Attached to the posterior surface was a firm, nodular, asymmetric mass about the size of a grapefruit The adnexa were normal

FIG 1 Solid and cystic masses of spindle-shaped cells in a dense hyalinized connective tissue stroma (300 ×)

Under spinal anesthesia, through a midline incision, a supravaginal hysterectomy and bilateral salpingo-oöphorectomy were performed

The specimen was attached to the posterior surface of the uterus at the level of the internal, a 15 by 13 by 7-cm nodular, encapsulated mass which, on microscopic section, proved to be a hyalinized fibromyoma Section through the ovary showed scattered small epithelial cell nests, some of which were solid, others cystic, with areas of ovum-like formation The cell nests were surrounded by a definite fibromatous stroma (Fig 2) Diagnosis was Brenner tumor of ovary and myoma of uteri

At a five-year follow-up, this patient was alive and well

Case 3—R S, age forty-eight, married, white, was admitted on January 13, 1948, because of increasing menorrhagia of four months duration She was a gravida III, Para 2 A diagnostic curettage, done in December, 1947, at another institution, was reported as showing early adenocarcinoma of the uterus Examination on admission revealed a uterus which was normal in size, shape, and consistency and freely movable

On January 18, 1947, under spinal anesthesia, a total abdominal hysterectomy and bilateral salpingo-oöphorectomy were performed.

Pathologic examination of the uterus showed no evidence of carcinoma. Section of the ovarian tumor nodule revealed epithelial islands, some of which had cystic centers and evidence of secretion They were located within a dense fibrous stroma and resembled pseudofollicles Diagnosis was Brenner tumor of ovary

Case 4—B S, a fifty-year-old white woman, was admitted February 18, 1948, because of progressively increasing menorrhagia since July, 1947 She was a gravida V, Para 3 Her last menstrual period was on February 1, 1948

Fig 2 Small epithelial cell nests surrounded by a fibromatous stroma (300 ×)

Fig 3 Two encapsulated cell nests surrounded by a well-defined fibromatous stroma (300 ×)

A preoperative diagnosis of fibromyoma uteri was made Under general anesthesia a supravaginal hysterectomy and bilateral salpingo-oöphorectomy were performed

Pathologic examination of the uterus showed a cellular fibromyoma The tubes and ovaries showed no gross pathologic changes Sections of one ovary contained two encapsulated epithelial cell nests surrounded by a well-defined fibromatous stroma (Fig 3)

The diagnosis was early Brenner tumor of the ovary

Summary

Four cases of Brenner tumor of the ovary are reported where the diagnosis was made only after pathologic examination of the operative specimens. In two instances (cases 2 and 4) the tumor was only an accidental finding associated with other primary gynecologic conditions for which the patients were operated

---

I am indebted to Dr Joseph Felsen director of the Department of Pathology and Medical Research Bronx Hospital for his helpful suggestions in the preparation of this report and to Dr A J Fleischer Dr H J Epstein and Dr Irving Smiley for their assistance

HEMATOMA OF THE UMBILICAL CORD

JEROME SCHWARTZ, M D , Bronx, New York

(From the Department of Obstetrics and Gynecology, Fordham Hospital)

HEMATOMA of the umbilical cord is an extremely rare complication of pregnancy In a review of the literature on the subject up to 1940, Dippel was able to collect only 36 cases [1] He states that the incidence of this rare abnormality of the umbilical cord is one in 5,505, at or near term Zamboni, however, in a study of 10,295 placentas did not find one hematoma of the umbilical cord [2]

Because of the rarity of this complication of pregnancy, the following case is reported

Case Report

A. F, a twenty-five-year-old white, gravida II, Para 1, clinic patient, was admitted on April 25, 1948, in active labor Expected date of confinement was April 19, 1948 In December, 1947, she had sustained a severe blow in the abdomen, and in January, 1948, she fell, striking on her abdomen These traumatic episodes were not accompanied or followed by either cramps or vaginal bleeding The prenatal course was otherwise uneventful

On admission, the uterus was enlarged to four fingers below the xiphoid process, vertex presentation, left occipitoanterior position with the presenting part unengaged Labor progressed normally, and patient was fully dilated seven and one-half hours after onset of labor At this time, the membranes ruptured with a gush of blood-stained amniotic fluid, immediately followed by vaginal bleeding of bright red blood Under pudendal block, the patient was immediately delivered of a living child that cried spontaneously Two loops of cord were noted loosely coiled about the baby's neck The placenta and membranes were delivered intact by the Brandt maneuver after a third stage of five minutes Bleeding ceased following delivery of the placenta. Estimated blood loss was about 200 cc

FIG 1 Hemotoma located on fetal surface of placenta enclosed between the amnion and chorion

FIG 2 Fetal surface of placenta with hematoma removed Silver wire passing through the point of rupture into umbilical vein

Examination of the placenta and membranes revealed the following The placenta was circular in shape, 18 cm. in diameter and weighed 454 Gm On the fetal surface of the placenta, enclosed between the amnion and chorion, was a large, irregularly wedge-shaped hematoma measuring 6 cm at its base Dissection of the umbilical vessels revealed a small longitudinal opening 1 cm. in length in one of the smaller umbilical veins This rent in the vessel was at a point 1 cm. from the fetal surface of the placenta (Figs. 1 and 2) Histologic examination of the vessel wall revealed a moderately thickened intima At one portion of the wall, a degenerative process had taken place in the muscularis with deposition of irregular small pieces of calcium amid splintered muscle and cloudy-appearing collagen The adventitia presented chorionic villi attached to its outer

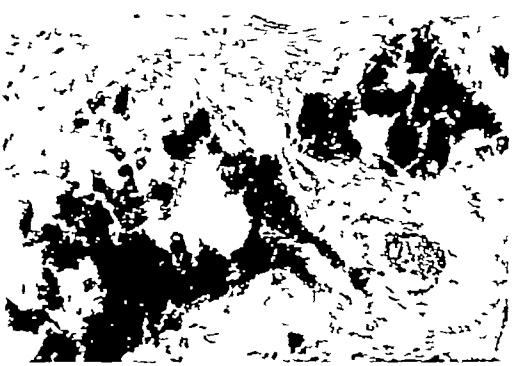

FIG 3 Vessel wall revealing deposition of irregular small pieces of calcium amid splintered muscle and cloudy-appearing collagen

Presented at a meeting of the Bronx Obstetrical and Gynecological Society January 24, 1948.

wall with trophoblastic cell nests and an occasional villus within the adventitial wall (Fig 3)

Comment

Rupture of the umbilical cord has been attributed to many causes absolute or relative shortening of the cord varicosities of the cord, trauma to the cord by the presenting part, passive congestion and diapedesis of blood, rupture of membranes, and intrinsic anomalies of the vessel wall [3–5] In our case, the collagen degeneration and calcification of the vessel wall resulted in weakness of the wall with eventual rupture at the weak point when subjected to the stresses of labor and delivery of the fetus

The hematoma is usually located near the umbilicus Dippel reported only one case where the hematoma originated within 5 cm. of the placenta It is this hematoma compressing the umbilical vessels with resulting anoxemia of the fetus that results in such a high fetal mortality Fifty per cent of all fetuses with hematoma of the cord are stillborn The fact that the hemorrhage in this case was primarily confined to the fetal surface of the placenta was an important factor in permitting us to obtain a living child, although there was the possibility that, if the patient had not delivered as soon as she did, following rupture of the membranes, the child might have exsanguinated via the ruptured vein wall

The diagnosis of hematoma of the cord is a difficult if not an impossible one to make prior to delivery, since there are no pathognomonic signs or symptoms that can be attributed to this accident, although fetal distress and vaginal bleeding prior to or during delivery are clinical evidences of a ruptured hematoma of the cord However, as these clinical signs are seen more frequently with other complications of pregnancy and labor, the diagnosis of hematoma will often be overlooked in favor of other more commonly occurring complications

Summary

1 A case is reported of hematoma of the umbilical cord, a rare complication of pregnancy and labor

2 The collagen degeneration and calcium deposition in the muscularis of the wall caused a weakening of the vessel wall which ruptured when subjected to the stresses of labor and delivery of the fetus

HEALTH STATISTICS AND HEALTH INSURANCE

The use of statistics to prove a case is an effective promotional device Somehow it always seems impressive even though we know the ambiguity of statistical findings Thus the figures on draft rejections were used to "prove" that the health of the American people was bad even though a large proportion of the rejections were for nonmedical reasons, and most of the remainder were for static defects (mental deficiency, for instance, or congenital deformities) which would never have been responsive to medical care anyway Government figures now show the health of the people to be at an all time high, though the same agencies which release the figures are also urging sweeping reforms to overcome "deficiencies" in medical care

Suppose an impartial observer wanted to measure the adequacy of compulsory health insurance by comparing morbidity or mortality figures In the first place, he would run into difficulty because no two countries are medically comparable Even if he were to dismiss this difficulty, he would still find the figures useless Or, more exactly, he would find the figures malleable to the point where he could prove anything The Research Council for Economic Security has actually studied health indices, and they offer us a fascinating grab bag of facts from which we can pull any conclusion we want For example, in 1938, New Zealand and France had compulsory health insurance programs, and the United States did not Infant mortality rates for the three countries were, respectively, 35, 66, and 51 This proves (*a*) Compulsory health insurance reduces infant mortality because the rate was 35 in New Zealand compared to 51 in the U S A , or (*b*) Compulsory health insurance means poor health, because the infant mortality rate was 66 in France compared with 51 in the United States If you used tuberculosis rates, you would get a similar set of figures How about life-expectancy? The health-insured French republic (prewar) had a male life expectancy, at birth, of 56, in the U S A it was 62, in New Zealand, 65½

Actually these figures *do* suggest something They indicate that climate, nutrition, and general living standards show a much closer correlation with morbidity and mortality rates than do methods of distributing medical care

Government efforts at improving health standards would be more effective if directed toward improvement in housing, nutrition, education, and living conditions generally Improvement in medical technics can safely be left to the medical scientist — *Editorial, Journal of the Medical Society of New Jersey, May, 1940*

ADENOMA OF BARTHOLIN'S GLAND

DAVID LAZARUS, M D , and ELY ELLIOTT LAZARUS, M.D , New York City

(From New York Polyclinic Medical School and Hospital)

CARCINOMA of Bartholin's gland is a rarity, only 79 cases having been reported in the literature up to 1947 However, if a review of the literature is an index, adenoma of Bartholin's gland is even more rare A careful review of the American and foreign literature from 1901 to 1948 has failed to reveal one reported case of adenoma of Bartholin's gland

Case Report

D L , thirty-one years old, white, married, presented herself with the chief complaint of swelling of the left labia Past history was negative She was a gravida I, Para 1, had started menstruating at the age of sixteen, with a normal cycle approximately every thirty days

Two and one-half years ago the patient noted a swelling in the left labia majora She was seen by a physician, and an incision and drainage of the mass was performed She was told she had a "cyst" Shortly after the operation, the patient noted that the mass was still there The mass had been growing since, more especially during the past eight months, when the increase in size had been more rapid There was no pain associated with the growth, no increased discharge, and no intermittent decrease in the size of the swelling

Physical examination revealed a well-developed, well-nourished white woman General physical examination revealed a swelling at the lower aspect of the left labia majora that measured approximately 3 by 2 by 2 cm. The mass was cystlike in consistency, except at the edges where it was somewhat firmer The mass was not tender and was well demarcated from the surrounding tissues with no adherence to the skin Pressure upon the mass did not cause any secretion to appear at the orifice of the gland No evidence of inflammation was present A moderate relaxation of the anterior and posterior vaginal walls was present The cervix was eroded The uterus was small, anteflexed, retrocessed, and the right ovary was cystic The diagnosis was recurrent cyst of Bartholin's gland

Operation was performed April, 1948, under sodium pentothal anesthesia. An incision was made at the mucocutaneous junction of the labia majora and carried down to expose the encapsulated wall of the mass which was dissected free from the surrounding tissue Brisk bleeding was encountered during this procedure The entire mass, which extended quite high, was removed in toto The bleeding was controlled, and the wound was closed with plain catgut

The pathologist's report was as follows The specimen consists of a small mass of tissue 4 cm in diameter It has a roughened surface and on section shows a pink-yellow structure Microscopic examination shows cyst wall containing numerous mucous glands and partially lined by stratified epithelium. The glands are hyperplastic, and there is some mononuclear infiltration (Fig 1) *Diagnosis* Bartholin's cyst, adenoma of Bartholin's gland

FIND WAY TO CHECK RADIATION HEMORRHAGE

A method of checking severe bleeding from radiation and in leukemia, cancer of the blood-forming tissues, has been reported by University of Chicago doctors who were awarded a gold medal in the 1948 scientific exhibit of the American Medical Association for the originality of their research

Toluidine blue and protamine sulfate was given by injection in three cases of radiation hemorrhage, and in all cases bleeding was stopped In one patient, a forty-year-old woman who had received x-ray therapy and four months of treatment with radioactive phosphorus for cancer, bleeding stopped eight hours after the first injection of toluidine blue

Although the drugs are not described as having a curative effect against leukemia, results against bleeding in leukemia patients are extremely favorable In seven of eight cases the bleeding was stopped, and in the remaining case it was lessened.

Hemorrhage after labor was stopped by the drugs in the five cases in which they were used. Two patients with hemophilia did not respond to the drugs

Findings suggest that hemorrhage in four other patients may have been related in part to endocrine disturbances, especially of the estrogens Hemorrhagic complications of these patients responded to toluidine blue and protamine sulfate

PRESIDENT'S ADDRESS—ANNUAL MEETING, 1949

LEO F SIMPSON, M D , Rochester, New York

IT HAS, indeed, been a great privilege for me to have served as your president this past year

I would, first of all, express my heartfelt appreciation to those who have worked with me Without their aid, without their loyalty, the load would have been too heavy It has been a rewarding experience for me, one which I shall ever cherish, and one for which I am humbly grateful

You will be honored next year by having Dr *John Masterson as my successor* He is able, wise, and courageous, and I know he will fully justify the wisdom of your House of Delegates in selecting him He will need your help Give it to him with your whole heart.

This last year has given me an opportunity to repay, in some small measure, the debt which I owe to medicine Medicine gives a man the *opportunity, if* he will, to follow a way of life that has been developed by generations of men, dedicated, as in almost no other tradition, to the service and welfare of their fellow men

There is considerable evidence that the well-earned love, honor, and respect which were given to our forebears in medicine are definitely on the wane in this country Especially is this true in the cities. It may be that other rewards, having greater value *in the market place, are more welcome*

There is even more evidence that a movement is on foot to take the control of our destinies away from us completely This would be pernicious, and a calamity for our patients. Under the A M.A. we are fighting this, with ever-increasing *intensity and at* great expense All programs of national education are costly, but we do it gladly, for the danger is immediate We carry within ourselves, however, the greatest aid to the campaign of the A.M A., one that is inexpensive and increasingly effective with the passage of time

We are trying to maintain the ideals of a great profession in what has grown to be one of the greatest industries in the United States—the care of the sick Surely the scientific capabilities of the doctor of today are far in excess of anything his forebears had to offer We have great medical schools and hospitals, fine doctors in these hospitals, in general practice, in clinics, in partnerships, in groups, a *great corps of specialists*—all striving to fill the need of good medical care We have created a multitude of tests, a horde of technicians to satisfy our scientific curiosity and to learn infinitely more about physical disease The quality of medical care is ever better, but it is, in addition, more expensive. I fear that it may be tending to become more impersonal, and so widen the gap between physician and patient

The thought occurs also that all of these facilities do not seem to be making very rapid headway toward the real goal of medicine, namely, a rapid decrease in the total amount of suffering in our patients. It seems to remain the same in quantity, although its forms may be changing In the opinion of the government, however, it would seem that we need vastly more of the same, even to stay in the race.

We are living in an age of tremendous unrest and change Formidable forces are at work with devastating rapidity New instrumentalities of science and invention are transforming our lives. Our efforts to keep our place in this modern and bewildering parade have left a large portion of our people tense, anxious, confused, and, I fear, willing to accept subsidy Couple this with the fact that man is the only animal with the peculiar knowledge that he is going to die, and you can see why our hospitals and offices are ever full of patients, ill both in body and in mind

All is changing but man himself In the mass he is essentially as he was centuries ago, and as one index of the present-day struggle we have the record that one person in thirteen in this country is being treated for some disease of the mind This, indeed, is a choice indictment. If this is any indication of our *future trend, we must quickly decide* whether the happiness of man or his prosperity should be our goal

That is why we must narrow the gap between the physician and the patient, for our patients' sake, for *our own sake, and for the sake of the great medical* profession as it fights the evils that beset it.

That is why it is so important that the practicing physician strive to occupy the place in society as depicted in Fildes' great painting, "The Doctor," and of Doctor McClure so wonderfully described by Ian Maclaren in his beautiful story, "A Doctor of the Old School "

That is why we must realize that psychosomatic medicine *is not a small part of medicine—it runs all through medicine*

That is why I have tried in my small way, during *the past year, to urge the immense practical value of the spiritual side of the practice of medicine, with*out which, in my opinion, we will die as a great profession and be transformed into one having an adding machine for its insignia rather than the caduceus—*and be treated accordingly*

I have spoken of the ever-present necessity of translating into action the virtues of charity, of unselfishness, of taking an intense personal interest not only in our patients' diseases, but also in their troubles, of ever, in all humility, becoming better artists in the care of the sick, in the care of the patient immediately at hand

When the physician exercises these virtues he closes the gap between himself and his patient Then he becomes the greatest public relations agent for the medical profession He will have, moreover, a great joy in living with himself, a consciousness of an ever-increasing value to humanity, and become the beneficiary of love and affection bestowed on only a chosen few

And what is more important, he can also be trusted ever to carry on high the torch of American medicine, a torch that should never be extinguished in any hostile environment

---

Presented at the Annual Meeting of the Medical Society of the State of New York Hotel Statler Buffalo May 4 1949 by the retiring president.

NECROLOGY

Theodore Prudden Bailey, M.D, ninety-one, died on May 22 at St Peter's Hospital, Albany Dr Bailey, who had lived in Albany for eighty-three years, was born in Casette, Alabama, and came to Albany as a small boy He studied for a time at West Point and received his medical degree from the College of Physicians and Surgeons, Columbia University, in 1880 Dr Bailey was a member of the New York State and Albany County Medical Societies and the American Medical Association

Nejib George Barbour, M D, a specialist in internal medicine, died on May 25 after a long illness Dr Barbour was eighty-three years old Born in Beirut, Syria, he studied at the American University at Beirut where he received his medical degree in 1887 and did postgraduate work in Paris From 1889 to 1894 he was assistant to Dr Cornelius Van Dyke at St George Hospital, Beirut, and in 1893 taught physiology and hygiene at the Greek College for Girls in Beirut

From 1916 until his death, Dr Barbour practiced in Brooklyn He was a former representative to the French consulate of the Libano-Syrian colony in the United States and from 1926 to 1932 was physician to the French Consul General. A Chevalier of the French Legion of Honor, Dr Barbour was a member of the American Medical Association and the New York State and Kings County Medical Societies

Salvatore Benanti, M D, seventy-three, a practicing physician in Brooklyn for more than thirty years, died on May 20 after a long illness Dr Benanti, a native of Italy, came to this country in 1905 and graduated from Long Island College Hospital in 1910 His internship and early professional years were spent in association with that hospital.

Since his retirement in 1941, he had devoted himself to literature, had written for various Italian publications, and was the author of three books Dr Benanti was a former member of the Kings County and New York State Medical Societies and the American Medical Association

Jacob Byer, M.D, of New York City, died on May 7 Dr Byer, a graduate of the University of Maryland School of Medicine and College of Physicians and Surgeons in 1932, was formerly adjunct physical therapist and assistant physician on the staff of Montefiore Hospital He was also a member of the New York State and County Medical Societies and the American Medical Association

Frederick A. Carpenter, M.D, ninety-three, New York State's second oldest practicing physician, died in May Dr Carpenter received his medical education at the Eclectic Medical College of Cincinnati, graduating in 1889 He began his practice in Middletown, New York, serving there as city physician and was also surgeon for the Grand Army of the Republic during that period In 1892 he moved to New York where he practiced until 1912 and was a member of the staff of the Nose and Throat clinic while there

In 1912 Dr Carpenter settled in Waverly where he was school physician for sixteen years, an examiner for the Metropolitan Life Insurance Company, and was an associate staff physician of the Tioga County General Hospital

Dr Carpenter was honored by the Medical Society of the State of New York in 1947 for his more than fifty years in the practice of medicine A past-president of the Tioga County Medical Society, he was also a member of the New York State Medical Society and the American Medical Association

Benjamin Milton Cissel, M D, died of a heart attack on May 31 at the age of fifty-six Dr Cissel received his medical degree from Johns Hopkins University School of Medicine in 1919, was appointed resident surgeon at the Long Island College Hospital the following year, and attending surgeon five years later In 1931 he joined the staff of Kings County Hospital and was appointed director of surgery in the Long Island College division of that hospital last August Dr Cissel was also a professor of clinical surgery at Long Island College of Medicine and director of surgery at Swedish Hospital, Brooklyn

Dr Cissel was a diplomate of the American Board of Surgery and a fellow of the American College of Surgeons and the New York Academy of Medicine. He was a member of the New York State and Kings County Medical Societies, the Brooklyn Surgical Society, and the American Medical Association.

David Leonard Cohen, M D, forty-seven, urologist and surgeon, died on June 1 After receiving his bachelor's degree at City College of New York where he was elected to Phi Beta Kappa, Dr Cohen enrolled in the school of engineering at Cornell University, later decided against this, and transferred to the New York University College of Medicine from which he was graduated in 1930 He interned at Beth Israel Hospital where he was a member of the alumni association and the junior medical board Formerly on the staff of the Montefiore Hospital, Bronx, at the time of his death Dr Cohen was assistant adjunct surgeon in the department of urology at Beth Israel Hospital.

Dr Cohen was a diplomate of the American Board of Urology and was a member of the American Urological Association, the American Medical Association, the New York State and County Medical Societies, and a fellow of the New York Academy of Medicine. In the second World War he served in the Middle East in the Army Medical Corps with the rank of major

Robert H. Fisher, M.D, seventy-seven-year-old former physician of Ithaca, died on May 26 Dr Fisher was graduated from the University of Buffalo School of Medicine in 1895 Retired in 1935 and since then a resident of Los Altos California, he had been the first health officer and coroner in Tioga County and was at one time president of the Village

of Spencer Formerly associated with Memorial Hospital, Ithaca, and a past-president of the Tompkins County Medical Society, Dr Fisher had also been a member of the American Medical Association and the New York State Medical Society

Elliott Moriarty Hague, M.D , seventy-nine-year-old Rochester physician, died on May 6 An associate staff physician at Genesee Hospital and Highland Hospital until his retirement several months ago Dr Hague was graduated from the University of Pennsylvania Medical School in 1897 He began practice in Rochester in 1898 and continued until his retirement when he moved to Buffalo Dr Hague was a member of the Rochester Academy of Medicine.

Eli Herr Long, M.D , a medical practitioner in Buffalo for more than forty years, died on May 31 at the age of eighty-eight. Dr Long a graduate of the University of Buffalo School of Medicine in the class of 1882, was a former professor at the schools of medicine, dentistry, and pharmacy of the University of Buffalo He was a member of the Buffalo Academy of Medicine, the New York State and Erie County Medical Societies, and the American Medical Association.

Alexander Mark, M.D , Elmira, died on May 18. Dr Mark was seventy-seven years old. At the time of his death he was a consultant physician on the staff of St. Joseph's Hospital, Elmira. He was a member of the New York State and Chemung County Medical Societies and the American Medical Association and had received his medical degree in 1899 from the Medico-Chirurgical College of Philadelphia.

Walter Latham Rathbun, M.D , seventy-year-old Cassadaga physician, died on April 28 after a long illness. Dr Rathbun was graduated from the Yale University College of Medicine in 1903 After having been in charge of the New York City Sanatorium at Otisville and the Stony Wold Sanatorium, Dr Rathbun, a native of Connecticut, settled in Cassadaga twenty-five years ago At Cassadaga Dr Rathbun helped develop and was active in the research and use of streptomycin treatment for tuberculosis. A special fund, named in his honor, was set up to be used in the purchase of the drug for needy patients and to permit continued research in its use at Newton Memorial Hospital. Dr Rathbun was formerly superintendent of the Newton Hospital.

Dr Rathbun was a member of the New York State and Chautauqua County Medical Societies, the American Medical Association, and the American Clinical and Climatological Society

William Dennis Scanlan, M.D., general practitioner in Brooklyn for the past thirty-eight years, died on May 29 at the age of sixty-eight. Dr Scanlan was graduated from the Long Island College Hospital in 1907 and served his internship at Kings County Hospital. He was a resident physician at Kingston Avenue Hospital for Contagious Diseases in Brooklyn and at the time of his death was assistant physician at Samaritan Hospital. He was also a member of the American Medical Association and the New York State and Kings County Medical Societies.

In 1903, following graduation from Syracuse University where he was a pitcher on the baseball team Dr Scanlan joined the Pittsburgh team of the National League. In 1904 he went to the Brooklyn team of the same league and pitched for them until 1907 and again from 1909 to 1911 In his best Brooklyn year Dr Scanlan won eighteen and lost twelve games.

John Joseph Shea, M.D , died on May 28. Eighty-two-year-old Dr Shea had practiced medicine in Greenwich Village, New York, from 1890 until his retirement ten years ago A native of New York City, Dr Shea was a member of the class of 1891 of the New York University College of Medicine

John Sherburne, M.D , fifty-seven, of Queens, died on May 23 after a long illness. Dr Sherburne received his medical degree from the College of Physicians and Surgeons, Columbia University, in 1919 and at the time of his death was a member of the staffs of Doctors' Hospital, New York, and St. John's and Mary Immaculate Hospitals in Queens. Dr Sherburne belonged to the New York State and Queens County Medical Societies and the American Medical Association.

Harry Knibb Tebbutt, Jr , M.D , Albany eye, ear, nose, and throat specialist, died on June 8 at the age of fifty-seven. After graduation from Albany Medical College in 1916, Dr Tebbutt served with Troop G New York National Guard, in the Mexican Border Campaign in 1916 He went to France in World War I as medical officer, Machine Gun Battalion 27th Division, with the rank of captain.

He had been attending otolaryngologist at Albany Hospital for the last twenty-five years and was also a consulting otolaryngologist on the staffs of Ludington Hospital, Ticonderoga, and Memorial Hospital, Catskill. He became assistant professor of otolaryngology at Albany Medical College in 1937 and was named associate professor in 1938 A diplomate of the American Board of Otolaryngology, Dr Tebbutt was a member of the Triological Society, honorary medical group, the American Medical Association, the American Academy of Ophthalmology and Otolaryngology, the American Laryngology, Rhinology, and Otolaryngology Society, and the New York State and Albany County Medical Societies.

HOSPITAL NEWS

Hospital Service in the United States

THE annual hospital report of the Council on Medical Education and Hospitals published in a recent issue of the *Journal of the American Medical Association* shows a new high in the utilization of hospital service in continental United States The present bed capacity of 1,423,520 and the average daily census of 1,217,154 are nearly identical with the previous report, but the total of 16,422,772 admissions in 1948 represents an increase of 593,260 in the last year and exceeds also the earlier record of 16,257,402 in 1945

While increases occurred in both the governmental and the nongovernmental divisions, the expansion was not uniform throughout the hospital field The federal hospitals, for example, reported a reduction of about 100,000 admissions, and the hospitals under "individual and partnership" control, 33,000, yet the governmental institutions as a group had a net increase of 86,147 and the nongovernmental hospitals 507,113

The admissions, as here reported, do not include hospital births, which last year totaled 2,794,281 compared with the all time record of 2,837,139 in 1947

The greatest increase in service was in the general hospitals, which reported 15,160,062 admissions and 2,715,645 births These totals represent 92 per cent of all patients admitted and 97 per cent of the hospital births in 1948 Although the bed capacity of this group was reduced in the last year from 592,453 to 576,459, the number of admissions increased by 494,867 With an average daily census of 437,590, the general hospitals in 1948 carried 36 per cent of the daily patient load reported in all registered hospitals

The psychiatric hospitals with a capacity of 691,499 beds admitted 305,000 patients, an increase of 13,046 compared with the previous year While this total represents less than 2 per cent of all admissions, the maintenance of an average daily census of 664,399 indicates that nearly 55 per cent of the occupied hospital beds are utilized for psychiatric care

An increase in tuberculosis hospitalization in the last year is apparent in the report of 105,588 admissions compared with 99,080 in 1947 The tuberculosis hospitals, which have a capacity of 81,993 beds, reported an average daily census of 66,484, or approximately 5 per cent of the total hospital load

Although the number of beds remained practically unchanged in the last year, the increase in hospital admissions did not result in a proportionate gain in the percentage of beds occupied This apparent discrepancy is clarified, however, by the reduced period of hospitalization in the general hospital group, to which 92 per cent of all patients were admitted In 1947 the average patient in a general hospital remained 11 4 days, while in 1948 the average length of stay was 10 5 Last year the over-all hospital occupancy rate was 85 5 per cent as compared with 85 4 in 1947 The percentage in the governmental hospitals increased to 89 0 per cent, but there was a corresponding reduction in the nongovernmental hospitals to 76 7 The general hospitals maintain an average occupancy of 75 9 per cent, but the increase to 96 1 in the psychiatric group indicates that many hospitals in this field operate well beyond their rated capacity

While modern hospitals are primarily engaged in the care of the sick, they are also to an increasing degree participating in educational functions necessary to the maintenance of high standards of hospital service The magnitude of this program is evident in the number of hospitals which have developed educational services for interns, resident physicians, student nurses, and hospital technical personnel. Currently there are 807 hospitals approved for interns and 1,140 for the training of resident physicians The accredited schools of nursing education, which now total 1,163, reported an enrollment of 100,174 student nurses in 1948 There are, in addition, 224 hospital schools approved for the training of x-ray technicians, 383 schools for medical technologists, 25 for occupational therapy technicians, 26 for physical therapy technicians, and 13 for the training of medical record personnel. The generous support which these educational programs have received is a further contribution on the part of the hospital administration and the medical, nursing, and technical staffs to the future needs of the hospital field.

Hospital Survey on Fires Planned

A NATION-WIDE survey of hospitals to reduce the loss of life from fire will be undertaken soon by the National Board of Fire Underwriters in cooperation with hospital and medical organizations, it has been announced.

The survey, which will cover 6,300 institutions and countless private nursing homes and is expected to take a year and a half, was decided upon as a result of the tragic fire on April 4 at St Anthony's Hospital, Effingham, Illinois, which took the lives of 73 persons, including 60 patients.

Directing the project will be a special committee on hospital inspection named by the executive committee of the National Board of Fire Underwriters and headed by Col. Perrin C Cothran of Hartford, Connecticut, vice-president of the Phoenix-Connecticut Group of Insurance Companies

Colonel Cothran emphasized that the inspections would be made entirely on a public service basis without regard to rates, premiums, or other commercial aspects of insurance.

The inspections, to be conducted by 6,000 fire prevention and safety engineers, will begin about July 15

The project will have the cooperation of the American Medical Association, the American Hospital Association and its Council on Hospital Planning and Plant Operation, the Association of Casualty and Surety Companies, and the National Association of Insurance Agents.

The plans contemplate directing inspections first to the hospitals considered most vulnerable to fire and loss of life from fire, or hospitals that are not fire-resistant or equipped with sprinkler and other protective features, Colonel Cothran said

The results of inspections will be furnished on a confidential basis to hospital administrators and other authorities In view of the interest expressed by hospitals and other authorities, it is anticipated that improvements will result

To prevent duplication of effort, inquiries now are being made to learn what general inspections of hospitals are under way or planned in various states and what machinery and organizations exist to perform inspection duties

Dr J J Golub, chairman of the American Hospital Association Council on Hospital Planning, said he hoped one of the results of the survey would be to point to the need for revision in building codes that would permit the wider use of modern fire preventive materials.

Dr Golub said he hoped also that it would give emphasis to the desirability of fire drills and training in evacuation procedures

Mental Hygiene Department Announces Building Plans

CONSTRUCTION has been completed and contracts awarded for several of the infirmaries and hospitals under the jurisdiction of the New York State Department of Mental Hygiene, which includes 27 institutions in the State The State's building program will increase the capacities of several of these institutions, which include 20 hospitals for the mentally ill and six schools for mental defectives

A total of $72,000,000 has been set aside for construction this year to provide additional beds, replace outmoded structures, and make available the most up-to-date facilities for the care of the 98,000 patients in the 27 institutions

Contracts totaling $8,109,770 have been awarded for construction of a 960-bed, Medical-Surgical Building at Hudson River State Hospital in Poughkeepsie, it was announced in a joint statement by Bertram D Tallamy, New York State Superintendent of Public Works, and Dr Frederick MacCurdy, State Commissioner of Mental Hygiene Construction of this new, nine-story modern hospital marks an important step in the initiation of the program to alleviate overcrowding in the mental hospitals urged by Governor Thomas E Dewey as one of the most pressing of the State's needs at this time Contract awards are pending for similar structures at State Hospitals in Buffalo and Binghamton

The first building completed under New York State's postwar construction program to increase facilities of the Department of Mental Hygiene is ready for occupancy, Dr Frederick MacCurdy, commissioner, announced The new building is a 200-bed infirmary at Craig Colony, the department's institution for epileptics, located at Sonyea, Livingston County

The infirmary, equipped with all modern facilities for complete medical care, was officially opened June 9 with an informal program to which directors and other personnel of several hospitals in the vicinity, also the general public, were invited

Dr Willard H Veeder, director of Craig Colony, indicated that moving of patients from other parts of the institution to the new infirmary will be started within a few days. The new building will not only alleviate overcrowding of Craig Colony generally, Dr Veeder pointed out, but will permit more efficient grouping of patients according to age

Craig Colony now houses approximately 2,224 epileptic patients, providing full medical care, including special treatment for convulsive disorders.

NEWS NOTES

At the Presbyterian Hospital, New York City, on June 13, a sculptured bust of the late Dr Hugh Auchincloss was presented to the hospital by members of his family The bronze head, the work of the sculptress Joy Buba, was presented by a brother, Mr Charles C Auchincloss, and accepted by Mr Charles P Cooper president of the hospital The humanity of Dr Auchincloss and his contributions to the advancement of surgery were described by his former associate, Dr Allen O Whipple, and two members of the School of Nursing spoke of Dr Auchincloss' gift of the Florence Nightingale memorabilia collection to the hospital.

Dr Auchincloss died on September 21, 1947, after more than thirty-five years' association with the surgical service of Presbyterian Hospital. He was among the first to perform a radical mastectomy, and he received world-wide acclaim for his monograph on infections of the hand. During the influenza epidemic of 1918, Dr Auchincloss won wide repute for introducing the "Auchincloss tube" for draining the pleural cavity

•

On July 1, Dr Thomas J Quigley will assume duties as medical coordinator at Saint Vincent's Hospital, Staten Island. A graduate of Georgetown University Medical School, Dr Quigley is a veteran of three years' service with the Army Medical Corps during World War II.

•

Dr Oswald S Lowsley, director of urology at the Brady Foundation of the New York Hospital, received Ecuador's national order, "Al Merito," with the designation of Commendador at a presentation ceremony held April 21 at the New York City home of Dr Homero Viteri-Lafronte, head of Ecuador's delegation to the United Nations

Dr Benjamin Jablons has been appointed visiting physician in peripheral vascular diseases at the Goldwater Memorial Hospital, New York City

On May 17 at the Manhattan General Hospital New York City, Dr Emanuel Revici presented a lecture on "Observations on the Administration of Lipids in Cancer"

The twenty-fifth anniversary of Unity Hospital Brooklyn was celebrated on April 23 with a dinner at the Waldorf-Astoria Hotel, New York City Speakers included Judge Jacob S Strahl, Justice Louis Goldstein and Dr George I Miller Dr Harry Apfel, president of the medical board for the past ten years, was presented with a bronze plaque Dr Meyer Scalar was toastmaster

Dr Samuel Feinstein formerly supervising psychiatrist at the St Lawrence State Hospital in Ogdensburg has been appointed assistant director clinical, at the hospital

Graduate staffs at the Bethesda and St James Hospitals, in Hornell, met on April 14 at the St James Hospital to hear a paper presented by Dr Leon M Roe, of Canisteo, on "Nursing Care in the Rehabilitation of Cerebrovascular Accidents."

•

Cornerstone ceremonies for the ten-story, 570-bed Kings County Tuberculosis and Chronic Disease Hospital, in Brooklyn, which will be part of the Kings County Hospital Medical Center, were held on June 10, with Mayor William O'Dwyer as principal speaker Dr Marcus D Kogel, City Commissioner of Hospitals, presided, and brief addresses were given by Borough President John Cashmore of Brooklyn, Dr Joseph Tenopyr, president of the medical board and director of surgery at Kings County Hospital, Dr Irwin E Sims, president of the Kings County Medical Society and the Academy of Medicine of Brooklyn, and Commissioner Frederick H Zurmuhlen of the Department of Public Works, under whose jurisdiction the hospital is being constructed.

The new hospital, estimated to cost $7,300,000 and scheduled for completion in the summer of 1950, is one of the several municipal hospital projects now under construction Others include the 300-bed Francis Delafield Hospital for cancer Manhattan, which will be affiliated with the Columbia-Presbyterian Medical Center, the 300-bed James Ewing Hospital for cancer, Manhattan, which will be affiliated with the Memorial Cancer Center, and the 2,000-bed Bird S Coler Chronic Disease Hospital and Home on Welfare Island.

Actual demolition ceremonies signaling the start of construction of the $32,744,000 building and development program of the New York University-Bellevue Medical Center were held on June 7 in New York City Construction of the Institute of Rehabilitation and Physical Medicine, first building to be started, is expected to get underway within a month, with completion scheduled by September 1950 The ceremonies opened with Mr Winthrop Rockefeller chairman of the Medical Center's Board of Trustees, giving the signal for wrecking crews to start demolition of the old buildings on the site. Among the speakers were Mayor William O'Dwyer and Dr Donald A. Covalt, clinical director of the Institute of Rehabilitation, representing Dr Howard A. Rusk, director of the Institute.

CORRESPONDENCE

To the Editor

The statement has been made rather frequently that Mr Bernard Baruch is in favor of compulsory health insurance

Accompanying this is a copy of a letter from Mr Baruch that refutes this statement This should be of interest to readers of our STATE JOURNAL in view of our stand in this matter

MADGE C L. MCGUINNESS, M.D
Chairman, Speakers' Bureau
Medical Society of the County of New York
51 East 87th Street
New York 28, New York
May 14, 1949

My dear Dr McGuinness

What I don't understand in all this talk about medicine is that everybody wants to go to the Government, even our own friends, to get aid Yet they expect that the Government is not going to call the tune as long as it pays the piper I certainly do not want to see what is generally known as socialized medicine As I said at the time of my address, I would oppose it with all my might I said, as you may remember, that the doctors have to get a move on themselves to meet the needs of the situation, and I stand on my speech I know that men like Dr Rawls are doing all they can to meet the needs of the situation without destroying the benefit the world derives from the great service the medical profession has always rendered

Yours very truly,
BERNARD M BARUCH

New York City

MEDICAL NEWS

Officers Elected to Head A.M.A

TWO members of the Medical Society of the State of New York were elected to office in the American Medical Association at the annual meeting held June 6 to 10 in Atlantic City, New Jersey Dr James R. Reuling, Bayside, treasurer of the State Society, was re-elected vice-speaker of the A M A. House of Delegates, and Dr Louis H Bauer, Hempstead, past-president of the State Society and now secretary of the World Medical Association, was re-elected to the A.M.A. Board of Trustees for a five-year term.

Dr Elmer L Henderson, of Louisville, Kentucky, was chosen president-elect, and will assume the office at the A.M.A annual meeting in San Francisco in June, 1950 Other officers chosen are Dr James Francis Norton, Jersey City, New Jersey, president of the Medical Society of New Jersey, vice-president, Dr George F Lull, Chicago, Illinois, secretary, Dr Josiah J Moore, Chicago, Illinois, treasurer, Dr Frank F Borzell, Philadelphia, Pennsylvania, speaker of the House of Delegates, and Dr F J L Blasingame, Wharton, Texas, trustee for a five-year term

Atlantic City, New Jersey, was announced as the convention city for 1951, and Chicago was selected as the meeting place for 1952 San Francisco, California, had previously been chosen as the 1950 site

A.M.A Sets Up Criteria for Medical Plans

AT ITS annual convention in Atlantic City, New Jersey, from June 6 to 10, the House of Delegates of the American Medical Association adopted a set of twenty suggested principles for lay-sponsored voluntary health plans, of which there are about eighty throughout the United States, with approximately one million subscribers

The principles are approved as suggestions to state and county medical societies, and these groups have the right to accept or reject the principles, to modify them, or ignore them

The twenty suggested principles for lay-sponsored voluntary health plans follow

1 The plan shall be nonprofit, pay no dividends to beneficiaries or others, all surplus earnings shall be devoted either to improving services, to making compensation of physicians and other staff members more adequate for their responsibilities and services, to purchasing facilities and equipment, to increasing the scope of benefits, or to building annual reserve funds. All income to the plan shall be devoted to services for beneficiaries.

2 The plan shall comply with the principles of medical ethics of the American Medical Association, which provide that it is unprofessional for a physician to dispose of his professional attainments or services to any lay body, organization, group, or individual, by whatever name called, or however organized, under terms or conditions which permit a direct profit from the fees, salary, or compensation received to accrue to the lay body or individual employing him.

3 If incorporated, the plan shall be adequately financed and organized without capital stock.

4. The plan shall be operated under an autonomous administration or trust, with segregated funds, and shall be devoted exclusively to the provision of health service

5 Promotion, sales, organization, and administrative expense of the plan shall be kept at a minimum as judged by the accrediting body

6 The quality of medical service shall be maintained at the highest possible level. All participating physicians shall be doctors of medicine duly licensed to practice medicine in any state in which the plan operates Each physician engaged in the practice of a specialty shall be required to have adequate qualifications for that specialty The personnel and facilities of the plan shall be adequate to insure a high quality of medical care.

7 The plan shall provide all services as set forth in the agreement with the beneficiary, save if in the opinion of the medical staff, a professional service set forth is not available because of an emergency or because of the need for highly technical procedure, or for any other reason, then such service shall be otherwise provided by the plan.

8 The plan, in its agreement entered into with the beneficiary and which shall be distributed to each beneficiary, shall state clearly the services and benefits to be provided and the conditions under which they will be provided. All exclusions, limitations, waiting period, and deductible provision shall be clearly stated in the agreement with the beneficiary and in promotional and descriptive literature

9 The plan shall, in its agreement with the beneficiary, state clearly the amount of dues or subscription to be paid The amount of dues or subscription shall be adequate to provide for the benefits and services offered and to insure proper financing of the risks involved

10 No promotional material shall invite attention to the professional skill, qualifications, or attainments of the physicians participating in the plan

11 Participating physicians may be compensated in any manner not contrary to the principles of medical ethics of the American Medical Association relating to contract practices

12 Any duly licensed physician in the community who wishes to participate in the plan, who meets its professional and personnel standards, and who agrees to abide by its terms and the requirements of its beneficiaries, shall be admitted to the plan.

13 The names of all participating physicians of the plan shall be made available to the prospective beneficiary The beneficiary shall, within reasonable geographic and professional limitations, have free choice among participating physicians

14. There shall be no interference by the governing body with the medical staff in the practice of medicine The traditional and confidential relationship of the physician and patient shall be preserved.

15 Adequate provisions shall be made for effective participation of the medical staff in the

deliberations of the governing body It is recommended that the membership of the governing body include representatives of the medical profession

16 All services rendered by the participating physician, not included in the beneficiary's contract, shall be payable by the beneficiary to the participating physician on a fee for service basis

17 The method of operation of any hospital owned or under contract to the plan shall be in accordance with sound public policy

18 The plan shall provide for like rates, benefits, terms, and conditions for all persons in the same class

19 Investment of reserve funds shall be made only in securities deemed prudent for such purposes

20 Any plan desiring approval under these principles shall agree to such periodic reviews and to abide by such regulations as may be deemed necessary by an appropriate accrediting body of the American Medical Association in consultation with representatives of the sponsors of the plan

Exchange Fellowships in Cancer Research

BRITISH-American Exchange Fellowships in Cancer Research of the American Cancer Society, awarded by the Society upon recommendation of the Committee on Growth of the National Research Council are offered to citizens of the United States for advanced training and experience in Great Britain in specialized fields of investigation pertaining to the problem of cancer Similar fellowships are awarded by the British Empire Cancer Campaign to British scientists for study in the United States The Society and the Committee on Growth welcome the cooperation of universities and hospitals in making known these opportunities to suitable candidates

These fellowships are awarded by the American Cancer Society to provide specialized training for American investigators in Great Britain where opportunities exist for study in facets of research in malignant disease not widely available in this country

Fellowships are open to citizens of the United States who possess the degree of Doctor of Medicine, Doctor of Philosophy, or Doctor of Science They are intended for young men and women embarking upon a career in clinical medicine or basic research, and also for more mature candidates desiring to extend their fields of competence in these fields Applicants must be able to demonstrate that they have qualifications necessary to pursue investigation in the fundamental sciences or in clinical medicine

Applications should state the institution where the fellow plans to work in Great Britain, the individual under whom the fellow desires to work, what problem he intends to investigate, when he wishes to start

Fellowships will be awarded for a period of one year The annual stipend will be £1,000 ($4,020) An allowance of $600 is made for travel to the site of the fellowship in Great Britain

University staff appointment, with teaching duties agreeable to the fellow, is permitted, provided it carries no additional salary and provided it is acceptable to the Committee on Growth, the American Cancer Society, and the British Empire Cancer Campaign No other remunerative work will be permitted during the tenure of the fellowship

Fellowship appointments are subject to the condition that, once accepted, they will not be vacated or the place of work changed within the period of tenure without the consent of the Committee on Growth, the American Cancer Society, and the British Empire Cancer Campaign

Application forms for British-American Exchange Fellowships in Cancer Research may be procured from and submitted at any time to the executive secretary of the Committee on Growth, Division of Medical Sciences, National Research Council, 2101 Constitution Avenue, Washington 25, D C Favorable action by the Committee on Growth takes the form of a recommendation to the American Cancer Society, and is subject to approval by the Society Fellowships will be made effective at the convenience of the institution and the fellow

MEDICALLY SPEAKING—

Life Insurance Medical Research Fund—The Life Insurance Medical Research Fund has published its fourth annual report on heart disease and heart disease research, addressed to members of the medical profession and to life insurance presidents of the United States and Canada.

Representing 147 life insurance companies, the Fund was organized late in 1945 as the first major organization in North America to devote its full resources to heart disease research In its first four years it sponsored nearly two million dollars of university and hospital work, and last month its Board of Directors voted to contribute another $600,000 during 1949

A summary of the Fund's activities through 1948 in its annual report shows that, for 1949, $585,300 more has been allocated for 53 new and old projects, and $94,700 has been awarded 27 new fellows, to bring the total Fund support of heart disease research so far to $2 576,000

The Electron Microscope—The first formal college program to train scientists to use the electron microscope and to explore the uncharted areas opened by the instrument is being organized in the Department of Engineering Physics at Cornell University

The project was disclosed by Dean S C Hollister of the College of Engineering in an announcement of plans for the establishment of a major Electron Microscopy Laboratory at Cornell The laboratory is being supported by a grant from the Rockefeller Foundation.

The laboratory will provide training in the field of electron optics and electron microscopy both in the fifth year of the undergraduate curriculum and at the graduate level. It will also make possible *fundamental research in electron microscopy* which is expected to result in development of new and improved technics

Announces Examination—The U S Civil Service Commission has announced examinations for positions at St Elizabeth's Hospital, Washington, D C, including a rotating internship (salary—$2,200 first year, $2,400 second year), psychiatric resident ($2,400 to $4,100 a year), and surgical resident ($3,400 to $4,150 a year) Further information and application forms may be obtained at most first- and second-class post offices, from civil service regional offices, or from the U S Civil Service Commission, Washington 25, D C

Establish Air Force Medical Reserve—General Hoyt S Vandenberg, Chief of Staff, U S Air Force, announced recently that applications are being received for commissions in the newly created Air Force Medical Reserve Physicians, dentists, nurses, and other medical personnel who served with the Army Air Forces during the war may make application through the Air Adjutant General, U.S Air Force, in Washington.

Texaco Fellowship in Industrial Medicine—The University of Cincinnati announces the creation of a Texaco Fellowship in Industrial Medicine, through a grant made to the Institute of Industrial Health in the Graduate School of Arts and Sciences by the Texas Company This fellowship is being established in the University and the Institute, in connection with the training of physicians for practice in industrial medicine and hygiene.

The Texaco Fellowship will be awarded for a two-year period, to begin July 1, 1949, and will provide for the intramural period of training of the successful candidate. On the completion of the work of the fellowship within the University, an additional year will be spent in supervised practice in one or more industrial organizations Upon successful completion of the entire course of training the degree of Doctor of Industrial Medicine will be awarded by the University

Research Fellowships—The American College of Physicians announces that a limited number of Fellowships in Medicine will be available from July 1, 1950 to June 30, 1951 These Fellowships are designed to provide an opportunity for research training either in the basic medical sciences or in the application of these sciences to clinical investigation They are for the benefit of physicians who are in the early stages of their preparation for a teaching and investigative career in internal medicine Assurance must be provided that the applicant will be acceptable in the laboratory or clinic of his choice and that he will be provided with the facilities necessary for the proper pursuit of his work. The stipend will be from $2,200 to $3,200 Application forms will be supplied on request to the American College of Physicians, 4200 Pine Street, Philadelphia 4, Pennsylvania, and must be submitted in duplicate not later than October 1, 1949 Announcement of awards will be made in November, 1949

Fellowships for Latin-American Physicians—The American College of Physicians and the W K Kellogg Foundation, with the cooperation of the U S Department of State and of medical schools in the U S A, Canada, and Latin-American countries, will shortly inaugurate a program of postgraduate medical fellowships Outstanding young physicians will be nominated to the College and Foundation by local committees in the countries to the south, and those to whom fellowships are awarded will be brought to this country for a year or more of special training It is anticipated that the first fellows will begin their studies during the autumn of 1949

Eligibility requirements include citizenship in the country from which application is made and familiarity with its culture and economy, graduation from an acceptable medical school and completion thereafter of an internship of 12 months or more, ability to use the English language, and assurance of a subsequent teaching affiliation with a medical school in the native country Those needing some training in English will be assigned to a special course for the purpose in the United States

Designed to stimulate progress in the teaching of internal medicine and research, and to help the most promising young doctors of medicine in these countries to prepare for teaching and research careers in their native countries, the program also will serve to increase understanding among the American republics by serving as a medium for the exchange of knowledge and acquaintanceships

Fellowships in Exfoliative Cytology—The American Cancer Society announces a series of fellowships available in various laboratories, including grants to the institutions as well as to individuals In New York City there are six fellowships available at Cornell University Medical College, and one at the New York Post-Graduate Hospital Individual applicants for fellowships should apply directly to the institutions—Dr George N Papanicolaou, at Cornell, and Dr Locke L Mackenzie, at Post-Graduate.

Board Adopts Requirements—The American Board of Preventive Medicine and Public Health, which is sponsored by the American Medical Association, American Public Health Association, Association of Schools of Public Health, Southern Medical Association, and Canadian Public Health Association, has adopted requirements for certification that are in harmony with those of the various specialty boards previously set up general qualifications, such as satisfactory moral and ethical standing in the medical profession, adequate medical training and internship in an approved hospital, and licensure to practice medicine in the United States To be eligible for examination, applicants must also have had special training and experience in preventive medicine and public health for at least six

years after internship (special academic training, or its equivalent, and field training or residency of at least two years of field experience in general public health practice, including planned instruction, observation and active participation in a comprehensive, organized public health program), each person to whom a certificate is issued must limit his practice to the teaching or practice of public health as a specialty

The standards thus set up appear to guarantee that diplomates of the new board will be men of the highest caliber in their field

City Health Department Checks Bathing Waters—The New York City Department of Health announced that it is taking water samples at 95 points along the New York City waterfront and making analyses of the samples as part of its continuing study of the City's bathing beaches Last year the Health Department, acting on instructions of the Board of Health, placed each of the City's beaches in one of four classifications

Those classifications are Class A, Group 1, "safe waters", Class A, Group 2, approved but subject to possible later reclassification in the light of continuing observation, Class B, "polluted beach waters not recommended for bathing" but where bathing is not actually forbidden, and Class C, those waters where bathing has long been prohibited.

The three factors taken into account in classifying a beach are (1) "epidemiologic experience"—that is, whether use of the waters for bathing and swimming has or has not caused illness, (2) the general sanitary conditions of water at each beach, and (3) the bacterial content of the water as established by analysis of samples taken under varying conditions

Albany Medical College Class Holds Reunion—Twelve physicians whose combined service to medicine totals 612 years met in Albany on May 14 for the fifty-first annual reunion dinner of the Class of 1898 of Albany Medical College The twelve, with three others who were unable to attend the dinner, are the remaining members of the class of 64 medical students Presiding at the reunion was Dr Edgar A. Vander Veer of Albany, who was president of the graduating class and has served for many years as the class alumni head Attending the dinner were Dr James F Rooney, Albany, Dr Charles S Prest, Brooklyn, Dr Robert W Andrews, Poughkeepsie, Dr James M Cronk, Hyde Park, Dr Julian A Gaul, Roxbury, New Hampshire, Dr David John Jenkins, Scranton, Pennsylvania, Dr Earl Parsons Lasher, Newton, Connecticut, Dr Roy Latham Leak, West Hartford, Connecticut, Dr Charles G McMullen, Niskayuna, Dr Nishan O Pashayan and Dr William J Swart, both of Schenectady Unable to attend were Dr Willard O Carpenter, St Petersburg, Florida, Dr G Worden Crissey, Mechanicville, and Dr George B Stanwix, Yonkers

National Commission on Chronic Illness Formed—The groundwork for the first concentrated attack on all aspects of chronic illness was laid in Chicago recently with the creation of a national Commission on Chronic Illness

Formation of the commission climaxed a year's preparatory work by four national voluntary associations in the medical, public health, hospital, and welfare fields to carry out one of the major recommendations of the National Health Assembly in May, 1948 These are the American Hospital Association, the American Medical Association, the American Public Health Association, and the American Public Welfare Association.

Briefly, the goals are

(1) To modify the prevailing attitude of society that chronic illness is hopeless, to substitute for the prevailing overconcentration on the provision of institutional care a dynamic program designed to prevent chronic illness, to minimize its effects, and to restore its victims to a socially useful and economically productive place in the community

(2) To define the problems arising from chronic illness among all age groups, with full realization of its social as well as medical aspects

(3) To coordinate separate programs for specific diseases with a general program designed to meet more effectively the needs common to all chronically ill persons

(4) To clarify relationships among professional groups and agencies working in the field of chronic illness

(5) To stimulate adoption in every state and community of a well-rounded plan for prevention and control of chronic illness and for the care and rehabilitation of the chronically ill.

Organized as a nonprofit corporation under the laws of Illinois, the Commission on Chronic Illness is appealing to foundations, professional societies, and other voluntary national organizations for funds It already has received $20,000 from the American Medical Association and $2,500 each from the National Society for Crippled Children and Adults and the New York Foundation.

MEETINGS

Past

American College of Chest Physicians, New York State Chapter

The New York State Chapter of the American College of Chest Physicians held its annual meeting in Buffalo on May 5 The following officers were elected Dr Joseph J Witt, Utica, first vice-president, Dr David Ulmar, New York City, second vice-president, and Dr Donald R McKay, Buffalo, secretary-treasurer

New York Council of Surgeons

The New York Council of Surgeons presented a lecture by Dr Daniel Burman, assistant visiting ophthalmologist at Fordham Hospital, New York

City, at a meeting held May 31 at the Parkchester General Hospital, the Bronx Dr Burman's subject was "The Diagnosis and Treatment of Diseases of the Eyelids and Related Structures"

Rudolf Virchow Medical Society in the City of New York

In commemoration of the two hundredth anniversary of the birth of Goethe, the Rudolf Virchow Medical Society in the City of New York sponsored a meeting at the New York Academy of Medicine on June 6 Scientific papers were presented by Dr Walter Fraenkel, Dr Bruno Kisch, and Dr Otto Meyerhoff An exhibit, "Goethe as a Scientist," arranged by the Rudolf Virchow Medical Society in collaboration with the Rare Books Department of the New York Academy of Medicine, was displayed at the meeting and throughout the month of June

Future

First International Congress of Biochemistry

The First International Congress of Biochemistry will be held at Cambridge University, Cambridge, England, from August 19 to 25, 1949 Twelve sections will be held, including "Animal Nutrition and General Metabolism," "Microbiologic Chemistry," "Enzymes and Tissue Metabolism," "Proteins," "Clinical Biochemistry," "Structure and Synthesis of Biologically Important Substances," "Cytochemistry," "Biologic Pigments Oxygen Carriers and Oxidizing Catalysts," "Hormones and Steroids," "Chemotherapy and Immunochemistry," "Plant Biochemistry," and "Industrial Fermentations"

American Congress of Physical Medicine

The American Congress of Physical Medicine will holds its twenty-seventh annual scientific and clinical session September 6 through 10, 1949, at the Netherland-Plaza Hotel, Cincinnati, Ohio All sessions will be open to members of the medical profession in good standing with the American Medical Association. Further information may be obtained by writing to the American Congress of Physical Medicine, 30 North Michigan Avenue, Chicago 2, Illinois

Medical Society of the State of Pennsylvania

The ninety-ninth annual meeting of the Medical Society of the State of Pennsylvania will be held September 26 through 29, 1949, at the Hotel William Penn, Pittsburgh, Pennsylvania.

American Public Health Association

The seventy-seventh annual meeting of the American Public Health Association will be held in New York City from October 24 to 28, 1949 The Hotels Statler and New Yorker will be joint headquarters Each of the thirteen sections of the Association is planning extensive scientific sessions in the field of its special interest The sections are dental health, engineering, epidemiology, food and nutrition, health officers, industrial hygiene, laboratory, maternal and child health, medical care, public health education, public health nursing, school health, and statistics

At the two evening general sessions, the Lasker Awards for 1949 will be presented, the Sedgwick Memorial Medal will be awarded, and the address of the president, Dr Charles F Wilinsky, director of Beth Israel Hospital, Boston, Massachusetts, will be read

A local committee, representative of health, medical, and civic groups in New York City, is being formed under the chairmanship of Dr Harry S Mustard, commissioner of health. Further details about the program may be obtained from Dr Reginald M Atwater, executive secretary, American Public Health Association, 1790 Broadway, New York City

American Association of Blood Banks

The second annual meeting of the American Association of Blood Banks will convene in Seattle, Washington, at the Olympic Hotel, on November 3, 4, and 5, 1949 Dr Ralph G Stillman, New York City, is president of the Association, and Dr Ernest Witebsky, of Buffalo, is vice-president

Further information may be obtained from the office of the Secretary, 3301 Junius Street, Dallas 1, Texas

National Society for Crippled Children and Adults

The annual convention of the National Society for Crippled Children and Adults will be held November 7, 8, and 9 at the Commodore Hotel, New York City Prominent authorities working in the field of the handicapped will present latest developments marking twenty-eight years of service for the Society Delegates from 2,000 state and local affiliates of the Society will discuss research, rehabilitation, training, and treatment for the handicapped

International College of Surgeons, United States Chapter

The thirteenth assembly of the United States Chapter, International College of Surgeons, will be held in Atlantic City, New Jersey, November 8, 9, 10, and 11, 1949, at the Chalfonte-Haddon Hall

PERSONALITIES

Honored

Dr Walter T Dannreuther, New York City, who received the Long Island College of Medicine Alumni Medallion for "Distinguished Service to American Medicine" at ceremonies held June 9 Dr Rehmi Denton, assistant resident physician in surgery at Albany Hospital, who has been named a research fellow of the American Heart Association and will work at Albany Medical College on a study of valvular heart conditions Dr W Yerby Jones, Buffalo, who received the Buffalo Urban League

Award for "Occupational and Professional Achievement" at the annual dinner of the group held recently in Buffalo

Dr John J Masterson, Brooklyn, president of the Medical Society of the State of New York, at a dinner on April 28 at the St George Hotel, Brooklyn, attended by three hundred friends and associates, at which tributes were paid by a number of speakers to the guest of honor for his long service to the medical profession of Brooklyn and in recognition of his election as president of the Medical Society of the State of New York Dr John J O'Connor, Jr, Island Trees, Long Island, and Dr Charles Mindell Plotz, Brooklyn, graduates of the Long Island College of Medicine, who were awarded scholarships by the New York Academy of Medicine, under the Bowen-Brooks Memorial Fund, to enable them to continue their postgraduate work. The Bowen-Brooks grants-in-aid are made only to young doctors who are graduates of New York City medical schools, and who have served or are serving on the house staffs of hospitals in the metropolitan area Dr O'Connor will use his scholarship to continue further special training at Kings County Hospital, and Dr Plotz will use his award to study arthritis for one year at Presbyterian Hospital

At the 1949 convention of the American Psychiatric Association, Dr Benjamin Pasamanick, in charge of the Children's Service of the Division of Psychiatry, Kings County Hospital, Brooklyn, and associate in psychiatry at the Long Island College of Medicine, received the first Lester N Hofheimer Research Award of $1,500, given to the psychiatrist under forty who has published the best research in the preceding three years Dr Emery A. Rovenstine, chairman of the department of anesthesiology, New York University-Bellevue Medical Center, who received the honorary degree of Doctor of Science at the 111th commencement ceremonies held June 5 at his alma mater, Wabash College, Crawfordsville, Indiana

Appointed

Dr Robert Boggs, as dean of the New York University Post-Graduate Medical School, effective July 1 Dr Boggs will administer the expanded program of postgraduate medical education made possible by the recent grant of over $8,000,000 to the Medical Center by the Samuel H Kress Foundation

Dr Geoffrey W Rake as medical director and Dr Asger F Langlykke as director of the Research and Development Laboratories of E R Squibb and Sons Dr Thomas R Noonan, assistant professor and head of the radiation physiology section, department of radiation biology, Atomic Energy Project, University of Rochester, to the staff of the Upjohn Company Medical Division

Elected

Dr Hollis E Clow, White Plains, as president of the American Geriatrics Society, and Dr Harold W Lovell, New York City, first vice-president as officers of the New York University College of Medicine Alumni Association—Dr Sydney Weston, president-elect, Dr Walter Levy, vice-president, Dr Richard M Hyman, secretary, and Dr Harold Brandaleone, treasurer Dr Henry M Scheer, New York City, former president of the Alumni Association of the New York University College of Medicine, as vice-president of the New York University Alumni Federation

Speakers

Dr Tibor de Cholnoky, on "Surgical Treatment of Malignant Tumors of the Face," by invitation at the Curie Institute, Paris, France, on June 22 Dr Michael Deddish, of the surgical staff of Memorial Hospital, New York City, and Dr R A. McTamaney, Newburgh, at a cancer forum held April 27 in Middletown, under the sponsorship of the Horton Hospital Auxiliary Dr Murray H Gardner, Watertown, at a meeting of medical representatives from chapters of the American Red Cross held in Syracuse, May 12, on the monthly needs for blood and plasma of hospital patients in Jefferson County and the present status of blood banks in the area.

Dr Marcus D Kogel, New York City commissioner of hospitals, on May 26 at the annual meeting of the Conference Group on Welfare of the Aged of the Welfare Council of New York City Dr Horace Miller, Utica, on "The Responsibility of the Osteopathic Physician to the Community" at a meeting of the Central New York Osteopathic Society held in Syracuse Dr George T Pack, New York City, lectures on "The Surgery of Gastric Cancer," "Endocrinology of Neoplastic Diseases," and "The Extension of Radical Surgery in the Treatment of Cancer," at the second cancer symposium sponsored by the University of Utah College of Medicine and the Bureau of Cancer Control of the State Department of Health held in Salt Lake City, Utah, April 26 and 27 also a series of lectures on neoplastic diseases and the conducting of two tumor clinics on the islands of Hawaii, Maui, Kauai, and Oahu, under the auspices of the Cancer Society of Hawaii and the Hawaii Territorial Medical Association.

Dr Cornelius P Rhoads, director of Memorial Hospital, New York City, on "Frontiers of Cancer Research" at a meeting of the Faculty Science Club of Hunter College, New York City, on May 9 Dr Helen Thompson, assistant professor of psychology at New York University-Bellevue Post-Graduate Medical School, on "Retarded Children as Individuals" at a meeting of the Association for the Help of Retarded Children held May 5 in New York City Dr William Trevor, New York City, in a debate on the question of "Socialized Medicine" before the East Side Branch of the Americans for Democratic Action on May 10, and on the same subject at a dinner meeting of the Whitestone Kiwanis Club on May 17

New Offices

Dr Nicholas J Czukor, formerly of Elizabeth, New Jersey, general practice in West Haverstraw Dr Reginald C Farrow, formerly of Syracuse, practice of surgery in Ithaca in association with Dr H Bruner Sutton, Dr John W Hirshfeld, and Dr James C Allanson Dr James Gray, formerly of Springville, general practice in Friendship Dr Joshua Kern, New York City, general practice in Fultonville Dr Theodore Perl, Binghamton, veteran of three years service in the Army Medical Corps with the 34th Infantry Division, practice of radiology in Syracuse

Dr Joseph Phelps, Deposit, veteran of four years service with the Army Medical Corps, three of which were in combat duty overseas, general practice in Edmeston Dr De Land Towner, general practice in Middletown

WOMAN'S AUXILIARY

TO THE MEDICAL SOCIETY OF THE STATE OF NEW YORK

Annual Convention Held in Buffalo

THE thirteenth annual convention of the Woman's Auxiliary to the Medical Society of the State of New York was held May 1 to 4 at the Hotel Statler, Buffalo, in conjunction with the 143rd annual convention of the Medical Society of the State of New York Mrs Edgar M Neptune, of Syracuse, presided, and there were 267 delegates, alternates, and guests registered at the convention

The program included sessions of the House of Delegates, meetings of the executive board, a county presidents' conference, and several social functions, including a supper party, a cocktail party, a luncheon, and a tea. Members of the Erie County Auxiliary were hostesses to the other auxiliaries, with Mrs Clarence J Durshordwe, Buffalo, as chairman of the convention committee

Mrs William J Lavelle, of Astoria, Long Island, former councilor for the Second District and a past-president of the Queens County Auxiliary, was inducted into office as president for the coming year Chosen as president-elect, to take office at the annual convention in 1950, was Mrs Hugh Henry, of Germantown, of the Columbia County Auxiliary

Other officers are Mrs Herman W Galster, Scotia, Schenectady County Auxiliary, first vice-president, Mrs Albert Vander Veer 2nd, Albany, Albany County Auxiliary, second vice-president, Mrs Thomas M d'Angelo, Flushing, Queens County Auxiliary, recording secretary, Mrs Arthur F Holding, Albany, Albany County Auxiliary, treasurer, and Mrs A Braunstein, Astoria, Queens County Auxiliary, *corresponding secretary*

District Councilors include District 1—Mrs Emerson Noll, Port Jervis, Orange County Auxiliary, District 2—Mrs Clifton Louis Dance, Brooklyn, Kings County Auxiliary, District 3—Mrs Ra Persons, Cairo, Greene County Auxiliary, District 4—Mrs E MacD Stanton, Duanesburg, Schenectady County Auxiliary, District 5—Mrs Philip I Turner, Utica, Oneida County Auxiliary, District 6—Mrs Manuel M Monserrate, Binghamton Broome County Auxiliary, District 7—Mrs Charle Miller, Rochester, Monroe County Auxiliary, an District 8—Mrs Arthur L Bennett, Buffalo, Erie County Auxiliary

Committee chairmen are archives—Mrs William Bartels, Garden City, Nassau County Auxiliary convention—Mrs Michael M Schultz, Hollis Queens County Auxiliary, finance—Mrs John J Rainey, Troy, Rensselaer County Auxiliary, historian—Mrs John J Buettner, Syracuse, Onondaga County Auxiliary, *Hygeia*—Mrs Edwin A Griffin Brooklyn, Kings County Auxiliary, legislation—Mrs John Horner, Albany, Albany County Auxiliary, national bulletin—Mrs Herbert Ensworth Ithaca, Tompkins County Auxiliary, organization —Mrs Albert Vander Veer 2nd, Albany, Albany County Auxiliary, parliamentarian—Mrs John L Mason, Pulaski, Oswego County Auxiliary Physicians' Home—Mrs George P Bergman Greenport, Suffolk County Auxiliary, *Distaff*—Mrs Adolph H Emerson, Brooklyn, Kings County Auxiliary, press and publicity—Mrs John L Neubert, Roslyn, Nassau County Auxiliary

Also printing and supplies—Mrs Walter A Schmitz, Middletown, Orange County Auxiliary program—Mrs Harold B Johnson, Buffalo, Erie County Auxiliary, public relations—Mrs Harry I Norton, Rochester, Monroe County Auxiliary, and revisions—Mrs Gerald Cooney, Syracuse, Onondaga County Auxiliary Special committee chairmen are board meetings—Mrs William G Richtmyer, Albany, Albany County Auxiliary, and clippings—Mrs Thomas E Bullard, Schuylerville, Saratoga County Auxiliary

State Medical Society Head Addresses Auxiliary

AT THE Monday afternoon session of the annual convention of the Woman's Auxiliary, May 2, 1949, in Buffalo, Dr Leo F Simpson of Rochester, president of the Medical Society of the State of New York, addressed the delegates and guests

The text of Dr Simpson's address follows

"Madam President, honored guests, and members of the Woman's Auxiliary of the State of New York

"I have been awaiting this opportunity to come before you to express my appreciation of the splendid work you have done and are doing for the Medical Society of the State of New York You have been busy at a multitude of tasks, helping our Society, helping your husbands, and acting as a cement that binds us all together Dr Beekman your staunch champion, never ceases to laud you and your efforts, and recently, at a meeting of the Council, he had a resolution enacted complimenting you on the preparation of the outlines entitled, 'Ladder to Auxiliary Success,' and 'What Every Doctor's Wife Should Know' Your paper, *The Distaff*, has also been increasingly informative and a pleasure to read

"American medicine, as you know, faces a crisis—the threatened passage of a National Health and Compulsory Insurance Act There is little I can say that will add to your knowledge of what the medical profession is doing to meet this threat

You all are familiar with the campaign we are conducting under the leadership of the American Medical Association This campaign represents the American profession's sincerest efforts to inform and alert the American public to the danger of such schemes to our patients, to themselves

"Recently, as you may know, we have had a very interesting experience in New York. Professor Reager, of Rutgers College, an instructor in speech, spent a couple of days with us giving instruction to nearly 175 doctors These doctors were all volunteer speakers for the cause, and I am sure when evening came we had 175 new missionaries, more eager and more competent because of that session If you can possibly use him, I commend him to you.

"I do not pretend to be either a sociologist or an economist Whatever special knowledge I possess lies in the field of medicine, and like most doctors I am only prepared to discuss medicine and its allied subjects With the passage of the years, however, I have become convinced that the doctor of today must supplement his knowledge of medicine with a knowledge of the social and economic problems which have arisen as medicine has progressed, and, incidentally, so must his wife

"The economic environment of our people is constantly changing, and is full of stresses The happiness of our people, the security of the American home must appeal to you, not only as doctors' wives, but as homemakers and mothers We know how prone we all are to mortgage our futures to have the material comforts that all consider so essential We know also the devastating economic effect of serious illness when it occurs in such homes The work of your organization in preaching, in and out of season, the value of voluntary hospital insurance, of voluntary medical care plans, has been of tremendous value These plans not only furnish life-saving protection at small cost, but also recruit an army of people who are with us in our fight against compulsory health insurance

"This is neither the time nor the place for me to reiterate the arguments against compulsory health insurance, nor to defend the present system of furnishing medical care to the American people, to speak of the stultifying influence of the one and the ever-expanding possibilities of the other You are already converted What the Medical Society of the State of New York needs is to make you into missionaries To do this, when you speak on this, and, in fact, when you speak on other subjects so necessary for the welfare of the medical profession, you must be prepared You will deal with audiences whose knowledge, whose interest, even, in your subject will be limited You cannot, however, underestimate their intelligence, their ability to ask searching questions You also have to be prepared to answer the occasional hostile person who may be present As Professor Reager would say, you must have an intimate knowledge of the material needed for a fifty-five minute talk in order to give one of five minutes

"If you are speaking against compulsory health insurance, in addition to your collateral reading the Public Relations Committee of the State Society can furnish you speakers' notes on cards which are packed full of information Perhaps you already have them.

"If you are speaking on voluntary medical care insurance plans, Mr Farrell of our bureau can give you invaluable material, and so with your other missionary efforts

"Zeal, enthusiasm, and determination will get you over the first hurdle and carry you ever onward These qualities are engendered by constant study, for before you can preach successfully you must know thoroughly, and believe in your heart

"These are platitudes, I know, but these platitudes I leave with you as my message today

"Our Auxiliary, composed of you gracious and important ladies, will continue to grow in numbers, and be ever alert and well informed You are our better half when we are with you and much more than that when we are not

"In conclusion, I would like to express not only my own appreciation, but also that of every member of the Medical Society of the State of New York for the wonderful work you have done during this past year

'I express this not only to Mrs Neptune, your president, to every state and county officer, but to each individual member of the auxiliary To Mrs Lavelle, your president-elect, I join with Dr Masterson in saying, 'welcome'"

COUNTY NEWS

Allegany County

The Allegany County Auxiliary met on May 12 in Belmont for a joint dinner meeting with the Allegany County Medical Society Annual election of officers followed the dinner, with the following results Mrs E Stanley Webster, president, Mrs Raymond O Hitchcock, vice-president, Mrs Philips J Morrison, secretary, and Mrs Edward J Briggs, treasurer Mrs Hitchcock and Mrs Irwin Felsen reported on their attendance at the State Auxiliary convention in Buffalo, May 2 to 4

Clinton County

The quarterly meeting of the Clinton County Auxiliary was held April 19 at the Nurses' Home of the Champlain Valley Hospital, with Mrs E W Sartwell presiding Mrs Sartwell, Mrs Andrew Speare, and Mrs Franklin Atwater were chosen delegates to the State convention

Erie County

At the monthly luncheon of the Erie County Auxiliary, held May 24, Mrs Ralph Upson, retiring president, presented the gavel to Mrs Clarence J Durshordwe, and installation of the other officers was held

Mrs Durshordwe appointed committee chairmen, as follows Mrs John A. Post, membership, Mrs J Frederick Painton, program, Mrs Elmer H. Stumpf, *Hygeia*, Mrs Hyatt Regester, public relations, Mrs Stuart L Vaughan, legislation, Mrs Roland B Carr, house and hospitality, Mrs Baxter Brown, press and publicity, Mrs George C Brady, historian, Mrs John R Hall national bulletin

Mrs Bernard Stell, telephone, Mrs Norman F Graeser, project, and Mrs Victor Cohen, finance

Reports were made on the year's activities, and the project committee reported that all the girls using Erie's scholarship loans have continued their high scholastic records By September, Erie County Auxiliary will have awarded eight loan scholarships, and two of the recipients will graduate in September

Madison County

Mrs Eugene W Carpenter was re-elected president of the Madison County Auxiliary at the annual meeting in April Other officers chosen are Mrs Lee S Preston and Mrs Charles Earl, vice-presidents, Mrs Felix Ottaviano, secretary, and Mrs Wallace Nicdorf, treasurer

At the May meeting, a luncheon was held at the Licklaen House, Cazenovia Mrs Carpenter presided, and guests of honor were Mrs John Mason, Pulaski, retiring Fifth District Councilor, and the new Councilor, Mrs Philip Turner, of Utica Mrs Bruce Storrs, Morrisville, was chairman of the arrangements committee for the luncheon

Nassau County

Mrs Clymer A Long, of Freeport, was installed as president of the Nassau County Auxiliary at the annual meeting held May 31 in Garden City Mrs John L Neubert, of Roslyn, is the retiring president

Other officers are Mrs Carl N Wechtel, Woodmere, president-elect, Mrs P A Robin, of Hempstead, and Mrs George Christmann, of Valley Stream, vice-presidents, Mrs Howard F Munro, Freeport, corresponding secretary, Mrs Joseph Kinnaman, Garden City, recording secretary, and Mrs Carl Freese, Garden City, treasurer

The annual bridge party of the Nassau County Auxiliary, a benefit for the welfare fund, was held June 23 at the Rockville Country Club

Onondaga County

At the annual spring luncheon of the Onondaga County Auxiliary, held May 17 in Syracuse, the following officers were elected for the coming year Mrs Neil M Paul, president, Mrs A Carl Hofmann, first vice-president, Mrs Foster C Rulison, second vice-president, Mrs Uri Doolittle, Jr, recording secretary, Mrs Herman Dick, corresponding secretary, Mrs Herman Harding, assistant corresponding secretary, Mrs Jerome Flatwo, treasurer, and Mrs Clifford Sorgues, assistant treasurer

Chairman for the luncheon was Mrs Joseph M Thornton, assisted by Mrs William J Ryan and Mrs Richard Vosburgh

At the April 12 meeting of the group, Mrs J Campbell Butler, executive director of the Central New York Medical Plan, Inc, discussed problems connected with the plan Mrs J Edward Kelly was hostess

Richmond County

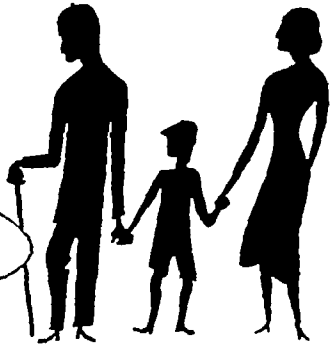
Mrs John J Goller was installed as president of the Richmond County Auxiliary at a luncheon held June 14 at the Villa Restaurant, Stapleton, succeeding Mrs Joseph F Worthen Other officers chosen are Mrs Leif G Jensen, president-elect, Mrs Lawrence E Viola, first vice-president, Mrs George E McCormack, second vice-president, Mrs Joseph M Malin, treasurer, Mrs. Joseph H Diamond, recording secretary, Mrs Henry W Litvak, corresponding secretary, and Mrs Vincent G Smith, historian

Schenectady County

New officers of the Schenectady County Auxiliary took office in June They are Mrs Milton Gipstein, president, Mrs Michael Slovak, president-elect, Mrs Kencil Mitton, first vice-president, Mrs Roland Faulkner, second vice-president, Mrs Donald McElroy, recording secretary, Mrs Thomas Adinolfi, corresponding secretary, Mrs Raymond Byron, assistant corresponding secretary, Mrs George Reich, treasurer, Mrs Herbert J Wright, Jr, assistant treasurer, and Mrs Donald Binder, historian

Seneca County

At the annual meeting of the Seneca County Auxiliary, held in Seneca Falls, officers were elected for the coming year They are Mrs Hyman Abrahamer, president, Mrs Arthur Baldwin, vice-president, Mrs Roy Wallace, secretary, and Mrs Saul Towers, treasurer



Westchester County

Mrs William Dick Sporborg, past-president of the Westchester, New York State, and National Federation of Women's Clubs, was guest speaker at the luncheon meeting of the Westchester County Auxiliary held May 23 in White Plains. Mrs Sporborg's topic was "Milestones on the Path to Peace"

Election of officers for the coming year was held at the meeting, with the following results Mrs Reginald A Higgons, Port Chester, president, Mrs Isadore Zadek, Mount Vernon, president-elect, Mrs Waring Willis, Bronxville, vice-president, Mrs Romeo Roberto, Yonkers, treasurer, Mrs Curtis T Prout, White Plains, recording secretary, and Mrs Donald W Richie, Croton Falls, corresponding secretary Mrs Laurance D Redway, Ossining, is the retiring president

A resolution opposing compulsory health insurance was unanimously approved by the Auxiliary, and copies were sent to the President of the United States, the New York State Senators, and the Westchester County Representatives

new name
new formula
new effectiveness

MYTINIC, Bristol's new and improved oral hematinic, retains the many advantages of VYTINIC, its forerunner in the field which has won such widespread acceptance. But additionally, the new formula includes almost double its previous iron content—in conformity with latest authoritative opinion—to insure optimum clinical response in iron-deficiency states.

MYTINIC is a clear amber solution which is outstandingly palatable. It is probably unique in providing so generously the several factors deficient in hypochromic anemia in a form so acceptable to patients of all ages. The suggested adult daily dose provides these multiples of the minimum daily adult requirements: Iron x 15, Thiamine x 15, Riboflavin x 3, plus adequate amounts of niacinamide and whole liver extract.

Mytinic
TRADEMARK

palatable hematinic

formerly Vytinic

MYTINIC CONTAINS PER FLUID OUNCE

Ferric Ammonium Citrate, NF	667 mg.
Thiamine Hydrochloride (Vitamin B_1)	10 mg.
Riboflavin (Vitamin B_2)	4 mg.
Niacinamide	100 mg.
Liver extract (derived from 20 Gm. of fresh liver)	1 Gm.

Dosage: Adults—one tablespoonful, t.i.d., with or immediately following meals, children—in proportion to age

Bottles of 12 fl. oz. and 1 gallon

May we send you a tasting sample?

ANNOUNCEMENTS

The following notices have been received from Dr Jacob L Lochner, Jr, secretary of the New York State Board of Medical Examiners, State Education Department, University of the State of New York

The Board of Regents, at a meeting held January 28, 1949,

Voted, That the action of the Board of Regents taken on September 17, 1948, in the matter of the application for the revocation of the medical license heretofore granted to Louis Klein, Hartford, Connecticut, be and the same hereby is amended and that medical license No 19485, issued under date of June 25, 1925, to Louis Klein, permitting him to practice medicine in the State of New York, be and the same hereby is revoked, annulled and canceled, and that his registration or registrations as a physician, wherever they may appear, be annulled and canceled of record, and that the Commissioner of Education be empowered and directed to execute, for and on behalf of the Board of Regents, all orders necessary to carry out the terms of this vote

Dr Louis Klein was served by registered mail with the order of the Commissioner on March 21, 1949, at 820 Pacoma Avenue, San Fernando, California

Voted, That, pursuant to the provisions of subdivision 1 of section 6514 of the Education Law, medical license No 19600 issued under date of June 25, 1925, to Samuel C Reiss, Brooklyn, permitting him to practice medicine in the State of New York, be revoked, annulled and canceled, and that his registration or registrations as a physician, wherever they may appear, be ordered annulled and canceled of record, and that the Commissioner of Education be empowered and directed to execute for and on behalf of the Board of Regents all orders necessary to carry out the terms of this vote

Samuel C Reiss was registered from 501 East 21st Street, Brooklyn, for 1947–1948 The order of revocation was served on Dr Reiss on February 14, 1949

Voted, That, pursuant to the provisions of subdivision 1 of section 6514 of the Education Law, medical license No 42260 issued under date of April 8, 1944, to Paul Singer, New York City, permitting him to practice medicine in the State of New York, be revoked, annulled and canceled, and that his registration or registrations as a physician, wherever they may appear, be ordered annulled and canceled of record, and that the Commissioner of Education be empowered and directed to execute, for and on behalf of the Board of Regents, all orders necessary to carry out the terms of this vote

Paul Singer was registered for the year 1947–1948 from 944 Park Avenue, New York City The order of revocation became effective as of February 23, 1949

Voted, That, the determination of the Medical Committee on Grievances in the matter of the application for the revocation of the medical license heretofore granted to Ferdinand Lustig, New York City, be accepted and sustained, that, in compliance with the recommendation of said committee medical license No 36764, issued under date of August 30, 1939, to said Ferdinand Lustig, permitting him to practice medicine in the State of New York, and his registration or registrations as a physician, wherever they may appear, be suspended for a period of one year from the date of service of the order effecting such suspension, and that the Commissioner of Education be empowered and directed to execute, for and on behalf of the Board of Regents, all orders necessary to accept the determination of said Committee on Grievances and to carry out the terms of this vote

Dr John S Lanese is registered with the Department for 1949–1950 from 137 Center Avenue, New Rochelle Dr Lanese appeared for censure and reprimand before the Board of Regents on April 22, 1949

Voted, That the determination of the Medical Committee on Grievances in the matter of the application for the revocation of the medical license heretofore granted to Samuel J Pashley, Hudson Falls, be accepted and sustained, that, in compliance with the recommendation of said committee medical license No 22877, issued under date of June 28, 1928, to said Samuel J Pashley, permitting him to practice medicine in the State of New York, be revoked, annulled and canceled, and that his registration or registrations as a physician, wherever they may appear, be ordered annulled and canceled of record, and that the Commissioner of Education be empowered and directed to execute, for and on behalf of the Board of Regents, all orders necessary to accept the determination of said Committee on Grievances and to carry out the terms of this vote.

Dr Samuel J Pashley was registered with the Department for 1949–1950 from 33 Catherine Street, Hudson Falls The order of the Commissioner was served on Dr Pashley on April 14, 1949, and his medical license therefore stands revoked as of that date

Voted, That the determination of the Medical Committee on Grievances in the matter of the application for the revocation of the medical license heretofore granted to Hermann Leslie Wenger, New York City, be accepted and sustained, that, in compliance with the recommendation of said committee, medical license No 17376, issued under date of September 28, 1922, to said Hermann Leslie Wenger, permitting him to practice medicine in the State of New York, and his registration or registrations as a physician, wherever they may appear, be suspended for a period of six months from the date of service of the order effecting such suspension, and that the Commissioner of Education be empowered and directed to execute for and on behalf of the Board of Regents all orders necessary to accept the determination of said Committee on Grievances and to carry out the terms of this vote

Dr Hermann Leslie Wenger was registered with the Department for 1949–1950 from 44 Gramercy Park, New York City The order of the Commissioner was served on Dr Wenger on April 18, 1949, and his medical license therefore stands suspended as of that date

The Board of Regents, at a meeting held May 20, 1949,

Voted, That the determination of the Medical Committee on Grievances in the matter of the application for the revocation of the medical license heretofore granted to George C von Borstel, Scotia, be accepted and sustained, that, in compliance with the recommendation of said committee, said George C von Borstel be censured and reprimanded, that said George C von Borstel be ordered to appear for such censure and reprimand before the Board of Regents at a time and place to be determined by the Commissioner of Education, notice of which shall be given to said George C von Borstel by said Commissioner, and that the Commissioner of Education be empowered and directed to execute for and on behalf of the Board of Regents, all orders necessary to carry out the terms of this vote

Dr von Borstel is registered for 1949–1950 from 101 Vley Road, Scotia The order was served on Dr von Borstel on June 2, 1949

You have one outstanding drug

for the treatment

of depression

In the depressed patient, 'Dexedrine' Sulfate can be depended upon to dispel the characteristic "chronic fatigue"; to induce a feeling of energy and well-being; and to restore optimism, mental alertness and capacity for work.

Dexedrine's anti-depressant effect is notable for its freedom from distracting elation, irritability and inward nervous tension. Its uniquely "smooth" action spares the patient the uncomfortable feeling of "drug stimulation".

REVIEWED

Diseases of Children Edited by Donald Paterson, M D, and Alan Moncrieff, M D Fourth edition (First edition edited by Sir A. E. Garrod, D M, Frederick E Batten, M D, and Hugh Thursfield, D M) Volume I, with contributions by twenty-nine contributors Octavo of 771 pages, illustrated Baltimore, Williams & Wilkins Co, 1947 Cloth, $9 00

This first volume which brings up to date the excellent and popular *Diseases of Children* by Garrod, Batten, Thursfield, and Paterson, is most welcome In much of its writing, particularly the material which deals with philosophic matters and clinical discussions, it is as charming and interesting as ever, therewith furnishing a pleasant supplement for those who wish to read pediatrics presented from the British point of view

An interesting transition has occurred in that certain American authors have written articles in this excellent text Thereby a quite different approach to certain scientific problems is offered We Americans like to believe that this is mutually beneficial

The section on infant feeding and diet will find less acceptance among American pediatricians than the other material in the book.

The appearance and setup of the book is excellent, as heretofore C A. Weyauller

A Textbook of Dietetics. By L. S P Davidson, M D, and Ian A Anderson, M B (Aberd) With Diet Sheets constructed by Miss Mary E Thomson, S R.N Second edition Octavo of 517 pages, illustrated New York, Paul B Hoeber, 1947 Cloth, $6 00

This is an excellent book on dietetics both from a theoretic and practical approach. It covers, in five parts, much of the present-day British food economy, the physiology of nutrition generally, as well as details about all vitamins, minerals, water metabolism, and composition of foods, diets for people under normal physiologic stress, the dietetic treatment of diseases, and diet outlines and recipes supporting the therapy suggestions and outlines The authors employ the tables of the National Research Council as basis for dietary food requirements

The reviewer considers this a good book but thinks that the economic surveys are too changeable to belong to a textbook. Morris Ant

Ophthalmology in the War Years. Vol II (1944-June, 1946) Edited by Meyer Wiener, M D Octavo of 977 pages Chicago, Year Book Publishers, 1948 Cloth, $16

This second volume of *Ophthalmology in the War Years* covers the period from January, 1944, to June, 1946, and, in the words of the editor, aims "to include everything of importance published during that time" These two volumes represent a most valuable contribution to ophthalmology of recent years.

The reader is impressed with the extensive bibliographies following each of the 33 chapters in this volume, each contributed by a different author or authors They have tried to provide a brief résumé of most of these many references For one who is preparing a paper or is involved in a research problem, this book is most valuable for reference. At any rate, one has before him a panorama of tremendous activity and progress in the field of ophthalmology Emanuel Krimsky

Monocular Vision Training By Mildred Smith Evans Quarto of 93 pages, illustrated. Baltimore, Williams & Wilkins Company, 1947 Cloth, $3 00

This home exercise book for children consists of lessons timed for a thirty-minute period for the treatment of strabismic amblyopia. The good eye is patched, and the child is instructed to trace various objects, to connect points making a figure, to read, and to differentiate colors.

The lessons are very ingenious and orientated to hold the child's curiosity and attention The progress of the patient may easily be determined by the parent or the orthoptic technician

Miss Evans has made another orthoptic contribution to the difficult problem of treating strabismic amblyopia. Of course, we must remember that surgery, if necessary, and orthoptics must work hand in hand in these cases Norris C Elvin

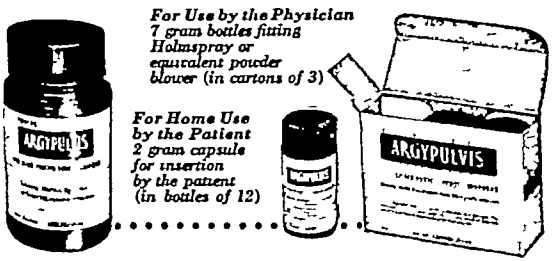
Strabismus A Clinical Handbook. By George J Epstein, M D Octavo of 214 pages, illustrated, Philadelphia, Blakiston Co, 1948 Cloth, $5 00

This monograph of 214 pages is instructive and well printed It will find a broad usefulness in the field of resident training It will doubtless be popular as its viewpoint is unusual Perhaps a future edition will justify inclusion of improved illustrations, particularly on pages four and five

A defect common to this book and practically all others on strabismus is the lack of real evidence from ordered studies to support positive statements

A more elaborate bibliography would be useful John N Evans

Handbook of Ophthalmology By Everett L Goar, M D Octavo of 166 pages, illustrated St Louis, C V Mosby Co, 1948 Cloth, $5 50



The author's aim in this elementary handbook of 162 pages was to provide his undergraduate students with an even simpler introduction to ophthalmology than is found in well-established manuals on the subject The first chapter deals with historical phases in ophthalmology which more advanced books fail to treat Otherwise, the subjects and arrangement follow the familiar pattern and are dealt with comprehensively and in simple language The medical student will be grateful for not being taxed with too much information Emanuel Krimsky

ARGYPULVIS 98% Effective in TRICHOMONIASIS

according to published report of Reich, Button and Nechtow, "Treatment of Trichomonas Vaginalis Vaginitis," *Surgery, Gynecology and Obstetrics*, May, 1947, pp 891-896 *

For Use by the Physician
7 gram bottles fitting Holmspray or equivalent powder blower (in cartons of 3)

For Home Use by the Patient
2 gram capsule for insertion by the patient (in bottles of 12)

• The technique included both office insufflation and supplementary home use of the powder in capsules, along with usual precautions against reinfection A most significant observation was that results from use of the capsules alone were approximately the same

Thus, this new form of dependable ARGYROL affords the physician a highly efficient weapon in the control of Trichomoniasis, through office and home treatment or by the patient's home use of capsules alone

Composition ARGYPULVIS contains powdered ARGYROL (20%), Kaolin (40%) and Beta Lactose (40%) finely milled to provide the fluffiness which makes for easy insufflation, and with an attraction for water which promotes fast action

Physical Properties

INTRODUCTORY TO PHYSICIANS *On request we will send professional samples of ARGYPULVIS (both forms) together with a reprint of the Reich Button and Nechtow report. (Use coupon.)

The Skull, Sinuses & Mastoids A Handbook of Roentgen Diagnosis. By Barton R. Young, M D Octavo of 328 pages, illustrated Chicago, Year Book Publishers, 1948 Cloth, $6 50

Medical students, physicians, roentgenologists in training—in short, anyone who wishes to inform himself speedily and conveniently about the roentgen technic and diagnosis of the skull, sinuses, and mastoids in health and disease, in children and adults, will find all that is of practical importance on the 314 pages of this book. The language is understandable and admirably to the point. The content is authentic The text is arranged in such a fashion that it can be studied simultaneously with the illustrations These illustrations are plentiful and of good quality SIEGFRIED W WESTING

A Handbook on Diseases of Children. Including Dietetics and the Common Fevers. By Bruce Williamson, M D Fifth edition Duodecimo of 408 pages, illustrated Baltimore, Williams & Wilkins Co , 1947 Cloth, $4 50

This compact handbook is a concise compendium on pediatrics Of necessity, brevity is the mainstay, so that even though practically every pediatric problem is touched upon, the surface of only a few diseases is penetrated.

Treatment does not form a major part of the work, and the newer antibiotics are treated all too sketchily

The value of the text lies in the rapidity with which one has available a brief review of pediatrics MARK J WALLFIELD

A Manual of Pharmacology and Its Applications to Therapeutics and Toxicology By Torald Sollmann, M D Seventh edition Quarto of 1,132 pages Philadelphia, W B Saunders Co , 1948 Cloth, $11 50

This classic manual of pharmacology has now appeared in a new revised seventh edition Numerous sections have been entirely rewritten or added for the first time Curare, "nitrogen mustards," BAL, and the antithyroid drugs are only a few which are now reviewed in this superb work.

ANDREW M BABEY

Gardiner's Handbook of Skin Diseases Revised by John Kinnear, M D Fifth edition Duodecimo of 250 pages, illustrated Baltimore, Williams & Wilkins Co , 1948. Cloth, $4 50

Written truly as a pocket manual for general practitioners, and as a helpful guide to nurses in the care of patients, this handbook is short and gives definite instruction in the method of application of remedies with the reasons therefor

It includes all of the common skin diseases, but naturally its description of them is short. It is, however, a valuable book for one with a very limited acquaintance with cutaneous diseases

E ALMORE GAUVAIN

Venous Thrombosis and Pulmonary Embolism. By Harold Neuhof, M D Octavo of 169 pages, illustrated New York, Grune & Stratton, 1948 Cloth, $4 50 (Mt Sinai Hospital Monograph No 2)

Dr Neuhof's book is a valuable addition to a growing list of useful American monographs It combines a scholarly review of the field of venous thrombosis and pulmonary embolism with a summary of the author's own observations extending over many years It will prove valuable, in spite of a rather poorly arranged text, to internist and surgeon alike MILTON PLOTZ

The Hospital Care of Neurosurgical Patients. By Wallace B Hamby, M D Second edition Octavo of 156 pages illustrated. Springfield, Ill., Charles C Thomas, 1948 Cloth, $3 00

A truly scientific and fine book on neurosurgical conditions, it is well illustrated and set up in a clear, concise manner The anatomy is clear and descriptive Each topic is well covered and organized, but unfortunately, it neglects to give any nursing care.

Physicians, as well as nurses, would profit by detailed nursing care because it differs from any other surgical condition This book should be in all hospital and nursing school libraries

MARIE M BEHLEN

Recent Advances in Medicine Clinical, Laboratory, Therapeutic. By G E Beaumont, M D , and E C Dodds, M D Twelfth edition Duodecimo of 422 pages, illustrated. Philadelphia, Blakiston Co , 1947 Cloth, $6 00

This is the twelfth edition of a well-known British contribution to clinical and laboratory medicine. It is so well-known and so reliable that scarcely anything needs to be said in its favor There are excellent new sections on vitamins, penicillin and other antibiotics, atypical pneumonia, hepatitis, and thiouracil

It is warmly recommended ANDREW BABEY

Practical Methods in Biochemistry By Frederick C Koch and Martin E Hanke Fifth edition Octavo of 419 pages, illustrated Baltimore, Williams & Wilkins Co , 1948 Cloth, $3 00

In its latest edition this laboratory manual presents the new and revised methods in biochemistry It includes chapters dealing with the various reduction, physical, and biologic tests on carbohydrates There are chapters on lipins, and estimation of proteins, amino acids, and hydrogen-ion concentration. There are practical experiments on the chemistry of salivary, gastric, and intestinal digestion The quantitative analysis of blood and urine, as well as the latest methods of colorimetric, fluorometric, and microbiologic estimation of vitamins and hormones are well described EDWARD H NIDISH

Urine and Urinalysis By Louis Gershenfeld, D Sc Third edition Duodecimo of 347 pages, illustrated New York, Romaine Pierson, 1948 Cloth, $5 00

The study of urine in health and disease is, of course, an important part of laboratory medicine Any volume which deals exclusively with this phase of the laboratory is worthy of notice The volume in question devotes over 300 pages to rare and common disorders as exemplified by the urine studies For that reason it is a good reference work

ANDREW BABEY

Bodies and Souls. By Maxence van der Meersch Translated by Eithne Wilkins Octavo of 654 pages Chicago, Pellegrini & Cudahy, 1948 Cloth, $3 75

New York *Times* review of this novel is captioned, "Scalpel versus Mammon" This does not seem an adequate summary of a fine novel in which doctors play almost all of the important roles The outstanding figure, in our estimation, is not the sacrificing son, with the tubercular wife and the high

[Continued on page 1602]

FROM SECRETARY OF DEFENSE LOUIS JOHNSON—

AN URGENT APPEAL TO YOUNG DOCTORS!

Your personal help is needed to avert a serious threat to our national security!

By the end of July of this year we will have lost almost one-third of the physicians and dentists now serving with our Armed Forces Without an increased inflow of such personnel, the shortage will assume even more dangerous proportions by December of this year

These losses are due to normal expiration of terms of service The professional men who are leaving the Armed Forces during this critical period are doing so because they have fulfilled their duty-obligations and have earned the right to return to civilian practice

Without sufficient replacements for these losses, we cannot continue to provide adequate medical and dental care for the almost 1,700,000 service men and women who are the backbone of our nation's defense

Normal procurement channels will not provide sufficient replacements!

To alleviate this critical, impending shortage of professional manpower in the three services, I am urging all physicians and dentists who were trained under wartime A S T P and V-12 programs under government auspices or who were deferred in order to complete their training at personal expense, *and who saw no active service,* to volunteer for a two-year tour of active duty, at once!

We have written personally to more than 10,000 of you in the past weeks urging such action The response to this appeal has not been encouraging, and our Armed Forces move rapidly toward a professional manpower crisis!

Many responses have been negative, but worse—a great number of doctors have not replied It is urgent that we hear from you immediately!

We feel certain that you recognize an obligation to your fellow men as well as to your profession in this matter We are confident that you will fulfill that obligation in the spirit of public service that is a tradition with the physician and dentist.

There is much to be said for a tour of duty with any of the Armed Forces You will work and train with leading men of your professions You will have access to abundant clinical material, have the best medical and dental facilities in which to practice You will expand your whole concept of life through travel and practice in foreign lands In many ways, a tour of service will be invaluable to you in later professional life!

Volunteer now for active duty You are urged to contact the Office of Secretary of Defense by collect wire immediately, signifying your acceptance and date of availability Your services are badly needed Will you offer them?

Louis Johnson

[Continued from page 1600]

medical morals, but his frustrated father who is not entirely honest in his interpretation of the results of his treatment of the insane by shock treatment and has later, to face most saddening domestic problems

The author practiced law before turning his talents to writing, but he has produced in this book a Balzac-like novel about doctors with an astounding wealth of medical detail—detail which is essentially accurate, but often of questionable appropriateness for the lay reader JOSEPH RAPHAEL

Vascular Diseases in Clinical Practice By Irving Sherwood Wright, M D Large duodecimo of 514 pages, illustrated Chicago, Year Book Publishers, 1948 Cloth, $7 50

This work is clearly and logically written in an easy-to-read, person-to-person style Many illustrations and case reports are well woven into the text. It is representative of the best in the modern clinical practice of peripheral vascular disease Emphasis is laid on the anticoagulant drugs The section on diagnosis and therapy of disorders of the veins is particularly well handled

JOSEPH R DIPALMA

Physiology of Exercise By Laurence E Morehouse, Ph D, and Augustus T Miller, Jr, Ph D Octavo of 323 pages, illustrated St Louis, C V Mosby Co, 1948 Cloth, $4 75

This descriptive book is well organized, clear, and well illustrated The glossary is most helpful

This book should be of great service to the physical education group but not appropriate for nurses The topic of exercise is not that fully covered in the nursing curriculum.

Since physical education has become such an essential part of the nursing program, the book might be placed in the nurses' library It would be a good reference book. MARIE M BEHLEN

Textbook of Gynecology By Emil Novak, M.D Third edition Octavo of 742 pages, illustrated Baltimore, Williams & Wilkins Co, 1948 Cloth, $8 00

An immense amount of information will be found in this well planned work. It is an excellent textbook for the student and a practical source of information for the practitioner who is concerned with diagnosis and treatment The illustrations are excellent, and the text may be read easily This sound textbook is highly recommended

CHARLES A. GORDON

The Medical Clinics of North America. Mayo Clinic Number July, 1948 Octavo Philadelphia, W B Saunders Co, 1948 Published Bi-Monthly (six numbers a year) Cloth, $16 00 net, paper, $12 net

The Mayo Clinic number of the *Medical Clinics of North America* includes an excellent five-paper symposium on anomalies of the heart. There are also nine other highly satisfactory clinics by various members of the Mayo staff The paper by Odel *et al* on clinical considerations of the problem of extrarenal excretion is of monographic proportions and will be of particular value to the practitioner who wishes to know more about this procedure.

MILTON PLOTZ

Treatise on Surgical Infections. By Frank Lamont Meleney, M D Octavo of 713 pages, illustrated. New York, Oxford University Press, 1948 Cloth, $12

The tireless efforts of Frank Meleney to solve the bacteriologic problems of surgery have won the admiration of all of us His comprehensive text will be eagerly read by every surgeon Its pages carry the complete story of bacterial invasion, our natural defenses, and the agents which we now marshal to repel the marauders The essentials of fine surgical technic are discussed This book is unique There has not been one like it CHARLES A. GORDON

Racial Variations in Immunity to Syphilis A Study of the Disease in the Chinese, White, and Negro Races By Chester North Frazier, M.D, and Li Hung-Chiung, M D Octavo of 122 pages, illustrated Chicago, University of Chicago Press, 1948 Cloth, $2 50

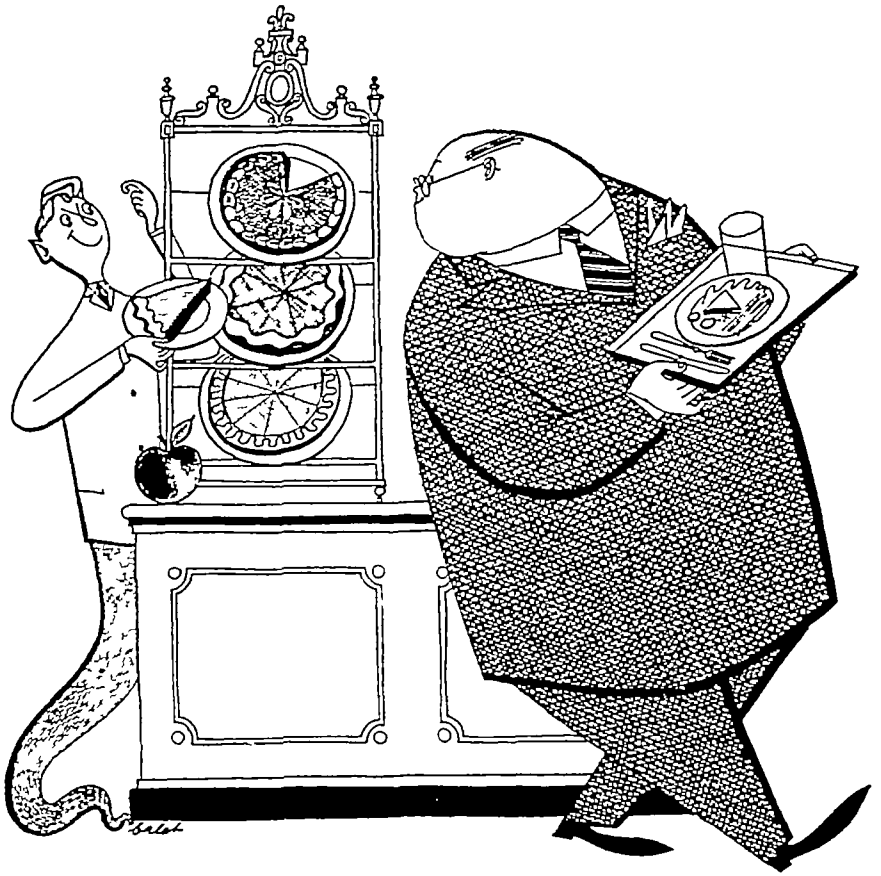
This book of only about one hundred pages is chockfull of statistics on this subject The authors have taken the records of Baltimore clinics, comprised of white and Negro patients with syphilis, to compare with cases of their own in Peiping, China There were approximately the same number of patients in all three racial groups

The studies investigated (and there are many tables of results) the incidence of syphilis in the three groups, dividing each into male and female cases They are classified according to the stage of the disease and the type of lesions occurring Among other conclusions, they determined that skeletal involvement in the Chinese is much more common than in the other two groups and believe this may be due to dietary inadequacies Meningitis is also more common among Chinese in early stages of the disease They also observed that there are probably greater differences depending upon sex than on race.

A reading of the text is certainly necessary to get the benefit of this profound and exhaustive study

E ALMORE GAUVAIN

Medical Hypnosis By Lewis R. Wolberg, M D In two volumes. Vol I, The Principles of Hypnotherapy, 449 pages Vol II, The Practice of Hypnotherapy, 513 pages Octavo New York, Grune & Stratton, 1948 Cloth, Vol I, $5 50, Vol. II, $6 50



In order to qualify himself for the gargantuan task of demonstrating the scientific value of hypnosis in medicine, the author has undoubtedly acquired all available knowledge on the subject and has compiled it into two volumes, the first of which is an authentic history of hypnosis from its inception to the present day, and the second a thoroughgoing study of its application to psychotherapy

In this work the author has evinced a great sensitivity to dynamic mechanisms of personality formation and an unusual skill in the application of all current technics to the treatment of mental cases The work is amply illustrated with clinical cases and dramatically reinforced with unusual clarity and precision The results obtained with this treatment in the hands of Dr Wolberg are often spectacular but are usually evaluated objectively and critically

Since the author assumes that hypnosis is a catalyst to psychotherapy rather than a substitute for it, he attempts to estimate as accurately as possible the depth of the induced hypnotic state that is most effective in achieving his therapeutic goal in each individual case Any student of this subject, interested in employing hypnosis in psychotherapy would do well to read these two volumes, which are both stimulating and instructive

SIMON ROTHENBERG

[Continued on page 1604]

how soon will he WEAKEN?

In another moment? tomorrow? next week? Whenever the break comes—as it will to most dieters exposed to continual temptation—DESOXYN Hydrochloride is a valuable aid in restoring the patient's will power • DESOXYN has a definite depressing action on the appetite At the same time, the stimulating action of the drug increases the patient s sense of well-being and desire for activity To depress the appetite, one 2 5 mg tablet an hour before breakfast and lunch is usually sufficient A third tablet may be taken in midafternoon if needed and if it does not cause insomnia • Those who have used DESOXYN extensively claim that it has these advantages over other sympathomimetic amines smaller dosage, quicker action, longer effect, and relatively few side-effects • In addition to use in obesity, DESOXYN may be given in a wide variety of conditions where a stimulant for the central nervous system or a long-acting vasopressor agent is needed For more details on the many indications for Desoxyn write ABBOTT LABORATORIES, North Chicago Illinois

[Continued from page 1602]

Peripheral Vascular Diseases Diagnosis and Treatment. By David W Kramer, M D Octavo of 620 pages, illustrated Philadelphia, F A Davis Co , 1948 Cloth, $8 00

In writing this second edition, Dr Kramer has considerably improved his book It is larger, more comprehensive and, as far as can be seen, has been practically rewritten The first section deals with a satisfactory and practical description of history-taking, physical signs, and special tests, with a sensible evaluation of the instrumental technics

The next section is devoted to a presentation of the occlusive vascular disorders It is difficult to accept Dr Kramer's persistence in treating cases of endarteritis obliterans as a separate entity from thromboangiitis obliterans It is generally accepted that they are pathologically and clinically one and the same disease

Then follow sections on vasospastic diseases, open lesions, and diseases of the veins and lymphatics His discussion of the therapeutic aspects of the diseases treated is sensible and up to date

W S COLLENS

Barbed-Wire Surgeon. By Alfred A. Weinstein, M D Octavo of 310 pages New York, Macmillan Company, 1948 Cloth, $3 00

This is a fine book It tells the story, and tells it well, of the experiences of the prisoners of war of the Japanese after the fall of Bataan and Corregidor Dr Weinstein makes no attempt to explain away defeats or plan campaigns He has confined himself to the important job of giving a medical man's description of the horrors and hardships of the men behind the "barbed wire" On the jacket, the publishers have boxed the plug, "It will be read wherever there are hearts that thrill to a magnificent story of courage and resolution" We are led to accept the boast, without reservation JOSEPH RAPHAEL

Midwifery By Ten Teachers under the direction of Clifford White, M D Edited by Clifford White, M D , Frank Cook, M B (Eng), and William Gilliatt, M D Eighth edition Octavo of 560 pages, illustrated Baltimore, Williams & Wilkins, 1948 Cloth, $6 00

This text has been deservedly popular for over thirty years, although, of necessity, changes have occurred in the names of the ten famous teachers Only the bare essentials of obstetrics are here, yet the presentation is excellent The importance of hemorrhage and the necessity for preparedness receives little attention CHARLES A. GORDON

The Salicylates. A Critical Bibliographic Review By Martin Gross, M D , and Leon A Greenberg, Ph D Octavo of 380 pages, illustrated New Haven, Hillhouse Press, 1948 Cloth, $6 00 (Monographs of the Institute for the Study of Analgesic and Sedative Drugs)

This book gives a detailed description of the salicylates It describes the occurrence of the salicylates in nature, their physical and chemical properties, and the incompatibilities There are chapters dealing with their analgesic and antipyretic effects The action of the salicylates on the blood and various organs of the body is given in detail, including their therapeutic and poisonous effects There is also a detailed bibliography of over four thousand references EDWARD H NIDISH

Hemolysis and Related Phenomena. By Eric Ponder, M D Octavo of 398 pages, illustrated New York, Grune & Stratton, 1948 Cloth $10

This monumental work will serve as a bible to all those working in hematology Here one will find authoritatively stated facts concerning hemolysis and related phenomena In seven well-documented chapters the author covers shape changes unaccompanied by volume changes, shape changes accompanied by volume changes, cytochemistry and architecture, kinetics of hemolysis, inhibition and acceleration of hemolysis and, lastly, hemolysis in vivo

It is impossible to review this book without a spirit of reverence for the author who has done so well to set the yardstick of our present knowledge of hemolytic phenomena MAURICE MORRISON

Standard Radiographic Positions By Nancy Davies and Ursel Isenburg Second edition. Octavo of 223 pages, illustrated Baltimore, Williams & Wilkins Co , 1948 Cloth, $6 00

This is a guide to proper positioning of patients for x-ray technicians It is written by two English radiographers The illustrations are simple hand drawings or reproductions of plans Much useful information can be found in this small volume

ANDREW M BABEY

The Back and Its Disorders. By Philip Lewin, M D Octavo of 157 pages, illustrated New York, McGraw-Hill Book Co , 1948 Cloth, $2 50

In his preface, Dr Lewin states that this book is written for the guidance of the general public rather than for doctors There may be no difference of opinion as to the need of such an appeal to the public, but it would seem that the doctor has crowded such a wealth of anatomic and pathologic detail in his 155 pages, with glossary, that he has somewhat overshot his mark and given the public more than it should be expected to understand Our impression is that medical men, those without special orthopedic training, might read this book, with profit, in the attempt to systematize their knowledge of that protean problem, "back pain"

JOSEPH RAPHAEL

Diseases of the Ear, Nose and Throat. By William Wallace Morrison, M D Octavo of 772 pages, illustrated New York, Appleton-Century-Crofts, 1948 Cloth, $8 50

Morrison's book on the *Diseases of the Ear, Nose and Throat* is well written, clear, and concise, with many illustrative diagrammatic sketches serving as visual aids in clarifying the various points under discussion This should be a valuable and instructive book to the student and general practitioner who wish to have a basic understanding and practical knowledge of the subject SYDNEY SHAPIN

General Endocrinology By C Donnell Turner, Ph D Octavo of 604 pages, illustrated Philadelphia, W B Saunders Co , 1948 Cloth, $6 75

This book is intended for advanced investigators and practicing physicians It gives the fundamentals of endocrinology It is a good basis for a complete understanding of endocrinology, coordinating the mechanism in plants, vertebrates, and invertebrates It is an erudite, excellent, concise accumulation of scientific data It has numerous illustrations

While the clinical aspects are not extensive, the other data will make for a rounding of clinical interpretation BERNARD SELIGMAN

[Continued on page 1606]

Peptic Ulcer...

control gastric acidity without Alkaline assault ...

Resmicon™

Peptic ulcer therapy with Resmicon through scientific application of the physical properties of resin and mucin places in the hands of the physician a new and remarkably efficient technic for control of gastric acidity

The special anion exchange polyamine resin contained in Resmicon *physically adsorbs excess acid* subsequently releasing the captured chloride ions in the alkaline environment of the intestine There is no violent chemical reaction with its resulting dyspepsia and the formation of astringent constipating by products Rapid reduction of acidity to physiologic levels is smoothly produced and efficiently maintained without danger of toxicity hyperalkalinization acid rebound or chloride loss,

The mucin component of Resmicon provides a tenacious protective coating resistant to the diffusion of acid and pepsin alike it produces a mechanical barrier against autodigestion

Of great importance in view of the etiologic role of pepsin in the production of gastric ulcer is the fact that both resinous and mucinous components of Resmicon tend to inhibit the action of this enzyme

In uncomplicated hyperacidity or in peptic ulcer Resmicon provides more efficient control than the customary alkaline antacids without their hazards

Resmicon is available in bottles of 64 tablets each tablet contains 500 mg anion exchange polyamine resin and 170 mg gastric mucin

Whittier LABORATORIES
Division Nutrition Research Laboratories
Chicago 30 Illinois

[Continued from page 1604]

Progress in Neurology and Psychiatry An Annual Review Vol III Edited by E A Spiegel, M D Octavo of 661 pages New York, Grune & Stratton, 1948 Cloth, $10

Both editor and publisher deserve unstinted praise for publishing this most valuable project composed of over 2,800 papers which are pertinently reviewed in this volume

The editorial board, assisted by outstanding contributors, has combed through the worthwhile literature on the four departments of the contents basic sciences, neurology, neurosurgery, and psychiatry Each of these departments has been assigned to outstanding authorities who not only present their own material but also that of their colleagues and document their contribution by references appended to each review

This annual review is a *sine qua non* to neuropsychiatrists as well as to the physician and student of medicine who obligate themselves to keep abreast of the rapidly growing research and practical applications of these specialties of medicine

FREDERICK L PATRY

Clinical Laboratory Methods and Diagnosis A Textbook on Laboratory Procedures with Their Interpretation By R B H Gradwohl, M D, and Dr Pedro Kourí Fourth edition In three volumes Quarto Vols I and II, 2,284 pages Vol III, Parasitology and Tropical Medicine, 864 pages Illustrated St Louis, C V Mosby Co, 1948 *Cloth, $40 set*

Student, teacher, and practitioner, alike, should find the revised volumes of accepted laboratory tests, with their interpretations and original references, a most valuable guide to modern laboratory diagnosis The division of the former text material into three separate volumes is of distinct advantage and is well worth the additional space which those volumes require The scope of clinical pathology has extended beyond the knowledge of any one authority The author's decision to publish three new volumes, with contributions by experts, to replace the one old one is symbolic of the rapid progress which this specialty has made in recent years. Distinguished authorities have revised and brought up to date the assembled material of their respective specialties The section on bacteriology has been almost completely revised Exfoliative cytology, especially vaginal smears for the diagnosis of cancer, is concisely but fully treated, from a practical standpoint The Rh factor is discussed with clarity, omitting controversial problems Parasitology is a separate volume which, by itself, is worth the price of the entire set. The plates are excellent, and the binding is attractive in color and very durable

S H POLAYES

Handbook of Treatment and Medical Formulary, By Charles M Gruber, M D Octavo of 585 pages Philadelphia, F A Davis Co, 1948 Cloth, $7 00

This is a sensibly well-bound, concise, and easily readable epitome of the latest knowledge that has come to us through the years of painstaking research in the fields of medicine, epidemiology, pharmacy, and therapeutics It is no scarehead cure-all in twenty-four hours, such as the popular so-called "lay medical articles' that have been appearing far too often in the lay press would have us believe is possible This is a concentrate of real knowledge, carefully and painstakingly screened out of all trash, boiled down and carefully skimmed of all the fat and froth, till we have the mother liquor which has stood the test of time and from which we can expect something but not too much No panaceas have been discovered, despite public clamor to the contrary, not even a twenty-four-hour cure for syphilis!

It is well worth a place in anyone's library or, better still, in the bag, for ready reference

THOMAS F NEVINS

The Discovery of the Orgone. Volume 2 The Cancer Biopathy By Wilhelm Reich, M D Translated by Theodore P Wolfe, M D Octavo of 409 pages, illustrated New York, Orgone Institute Pr, 1948 Cloth, $8 50

The author of this volume claims to be the discoverer of the existence of a basically new form of cosmic energy which he calls "orgone" Armed with this approach, he attempts to solve the problem of cancer by methods that, to the current ways of scientific thinking, are, to say the least, distinctly unconventional

While much of the book is incomprehensible to the reviewer, certain facts, namely those dealing with "orgone biophysical" blood tests for cancer, fall within the scope of his laboratory knowledge, and for that reason it can be safely said on *a priori* grounds that such laboratory tests as blood cultures, the biologic resistance tests, and possibly the disintegration test of red cells in physiologic salt solution are quite unfounded in laboratory fact For this and other reasons, it seems safe to say that this book cannot be regarded as contributing toward the solution of the cancer problem as it is conventionally understood by the medical profession

THEO J CURPHEY

The Digestive Tract in Roentgenology By Jacob Buckstein, M D Quarto of 889 pages, illustrated. Philadelphia, J B Lippincott Co, 1948 Cloth $16 00

The tremendously large material of Bellevue Hospital forms the basis of this volume whose greatest usefulness will be for readers seeking authentic information on rare diseases, for instance, syphilis of the stomach The novice desirous of acquainting himself with alimentary tract roentgenology also will derive benefit from this well-written, well-documented, well-illustrated, and rather complete presentation

The author seems overcritical regarding the mucosa study of the digestive tract which, in the reviewer's opinion, deserves more emphatic recommendation The roentgenography of the lower pharynx, so often omitted in books and in the daily work, has been given due consideration

SIEGFRIED W WESTING

An Index of Treatment by Various Writers Edited by Sir Robert Hutchison, M D Assisted by Reginald Hilton, M D Thirteenth edition Octavo of 972 pages, illustrated Baltimore, Williams & Wilkins Co, 1948 Cloth, $17

This is the thirteenth edition of a deservedly popular British compendium of treatment modeled on French's *Differential Diagnosis* Many of the best figures in England are contributors As usual, the material is clearly and well written, although necessarily brief

This volume is recommended for the wealth of sound, conservative therapy presented

ANDREW M BABEY

Practice of Allergy By Warren T Vaughan, M D Revised by J Harvey Black, M D Second

[Continued on page 1608]

True in '38

"Because of the convenience, smaller adequate dose, and better tolerance, the trend is toward the use of ferrous sulfate"

Stelke, E L Rhode Island M.J 21 61 (April) 1938

True in '48

"No iron preparation has proved superior to ferrous sulfate, with respect either to economy or efficacy"

Emerson, C P, Jr M Clin North America 32 1264 (Sept) 1948

and True Today

There are many iron preparations, but only Feosol Tablets provide ferrous sulfate with the special, S K F -developed vehicle and coating that—

1. prevent oxidation of the ferrous sulfate into the inferior ferric form
2. assure prompt disintegration in the acid medium of the stomach and upper duodenum, where iron absorption is best

Each Feosol Tablet contains 3 grains exsiccated ferrous sulfate—the equivalent of approximately 5 grains crystalline ferrous sulfate

Feosol Tablets

the standard iron therapy

Smith, Kline & French Laboratories
Philadelphia

[Continued from page 1606]

edition Quarto of 1,132 pages, illustrated St. Louis, C V Mosby Co , 1948 Cloth, $15

This revision by J Harvey Black of Warren Vaughan's outstanding book on *Practice of Allergy*, published first in 1939, is most welcome It retains the excellent qualities of the original and adds some of the more recent developments in the field

Noteworthy additions are O C Durham's chapters on the newer technics for pollen counting and on the results of country-wide pollen surveys Ragweed pollen indexes for the entire country are included The chapter on skin testing is unusually complete

The revised book retains its position as one of the best in the field of allergy MATTHEW WALZER

Occupational Therapy Source Book. Edited by Sidney Licht, M D Octavo of 90 pages Baltimore, Williams & Wilkins Co , 1948 Cloth, $1 00

This book is written to urge the further use of occupational therapy in the treatment of mental diseases The question of occupational therapy is dealt with from ancient times to the present A strong plea is made that occupational therapy be utilized to a greater extent and this with justification after viewing the results of the use of therapy

ARTHUR D JAQUES

Polio and Its Problems. By Roland H Berg Octavo of 174 pages, illustrated Philadelphia, J B Lippincott Co , 1948 Cloth, $3 00

Here is an intensely absorbing history of polio from the time it was first recognized The successes and failures of men of science who persistently tried and are still working to find the cause and cure of infantile paralysis are described dramatically

This book should be equally interesting to laymen and those of the medical profession

It should be a further means of keeping "polio" before the American public until it is conquered

JOHN A. MONFORT

Synopsis of Pediatrics By John Zahorsky, M D , assisted by T S Zahorsky, M D Fifth edition Duodecimo of 449 pages, illustrated St Louis, C V Mosby Co , 1948 Cloth, $5 50

This must have been a very timely book in the days of Tr Ferri Chloride and Ichthyol ointment Both of these remedies are strongly recommended by the authors Empyema is still being treated by thoracotomy and "a mortality of 25 per cent to 30 per cent is to be expected " The modern treatment of empyema by aspiration and penicillin injections is not even mentioned We are told by the publisher that this is a new book The chapter on asthma is equally amateurish if not misleading in its symptomatology

After perusing some of the more representative chapters, the reviewer is forced to the conclusion that this book is quite obsolete It is not fair to offer this to the student of medicine as a modern work

HARRY APFEL

Recent Advances in Anaesthesia and Analgesia (Including Oxygen Therapy) By C Langton Hewer, M B (Eng) Sixth edition Duodecimo of 380 pages, illustrated Philadelphia, Blakiston Co , 1948 Cloth, $6 00

In this small volume an attempt is made to embrace the whole field of anesthesiology which, of course, makes each part of the book inadequate because of its too wide scope

There are chapters on shock, cardiac massage, methods of nerve blocking, as well as others on oxygen therapy and resuscitation Each of these, actually containing only an occasional point is insufficient by itself However, the work is well illustrated, and some of the line drawings are illuminative

This book could serve as an introduction to the field of anesthesiology F PAUL ANSBRO

Detailed Atlas of the Head and Neck By Raymond C Truex, M S , and Carl E Kellner Folio of 162 pages, illustrated New York, Oxford University Press, 1948 Cloth, $15

This atlas is the culmination of many years of diligent and careful dissections by Professor Truex, portrayed by the artist, Carl E Kellner, whose reproductions are almost "lifelike " We remember well the difficulties we had with our studies in anatomy and with our dissections, so we are indeed in a position to appreciate first hand the serial dissections and their artistic reproductions in this book. Those of us who are particularly interested in the anatomy of the head and neck will indeed enjoy a refresher course by the study and the much needed reference to this volume The head and neck surgeon can profit well by a study of the detailed dissections of the area which he is about to explore surgically We were helped materially by the fact that each structure was carefully identified with the naming of these structures directly on the illustrations which were beautifully done in color An atlas of this type should be in every hospital and every doctor's library SAMUEL ZWERLING

Pediatric Nursing By Gladys S Benz, R.N Octavo of 638 pages, illustrated St Louis, C V Mosby Co , 1948 Cloth, $4.00

This is more than a book on nursing It is a reference work on the care of children at home as well as at the hospital It contains valuable information on sex education and a detailed discussion on entertainment for children

Ample space is devoted to the prevention and care of communicable diseases This book is well fitted for advanced study The book is well written, but it also contains superfluous material, e g , 101 pages are devoted to the bibliography on relevant subjects It is also profusely illustrated

HARRY APFEL

The Clinical Management of Varicose Veins By David Woolfolk Barrow, M D Octavo of 155 pages, illustrated. New York, Paul B Hoeber, 1948 Cloth, $5 00

This well-written, short survey of the treatment of varicose veins and their allied complications can easily be read with sustained interest at one sitting

Controversial questions are eliminated and the modern concepts presented Numerous photographs and diagrammatic representations make reading matter readily understandable In extensive varicosities and in complicated conditions, high saphenous ligations, with stripping, is the treatment recommended as decreasing the incidence of recurrence The book is highly recommended

HUGH L MURPHY

Your Baby The Complete Baby Book for Mothers and Fathers By Gladys Denny Shultz and Lee Forrest Hill, M D Quarto of 237 pages, illustrated New York, Doubleday & Co , 1948 Cloth, $3 50

Your Baby is a storehouse of information for mother and father From the first month of preg-

Manufacturers of NUCARPON ® Compound Charcoal Tablets for Intestinal Dysfunction

STANDARD PHARMACEUTICAL CO., INC., 1123 Broadway, New York

[Continued from page 1606]

edition. Quarto of 1,132 pages, illustrated St Louis, C V Mosby Co, 1948 Cloth, $15

This revision by J Harvey Black of Warren Vaughan's outstanding book on *Practice of Allergy*, published first in 1939, is most welcome It retains the excellent qualities of the original and adds some of the more recent developments in the field

Noteworthy additions are O C Durham's chapters on the newer technics for pollen counting and on the results of country-wide pollen surveys Ragweed pollen indexes for the entire country are included The chapter on skin testing is unusually complete

The revised book retains its position as one of the best in the field of allergy MATTHEW WALZER

Occupational Therapy Source Book. Edited by Sidney Licht, M D Octavo of 90 pages Baltimore, Williams & Wilkins Co, 1948 Cloth, $1 00

This book is written to urge the further use of occupational therapy in the treatment of mental diseases The question of occupational therapy is dealt with from ancient times to the present A strong plea is made that occupational therapy be utilized to a greater extent and this with justification after viewing the results of the use of therapy

ARTHUR D JAQUES

Polio and Its Problems. By Roland H Berg Octavo of 174 pages, illustrated Philadelphia, J B Lippincott Co, 1948 Cloth, $3 00

Here is an intensely absorbing history of polio from the time it was first recognized The successes and failures of men of science who persistently tried and are still working to find the cause and cure of infantile paralysis are described dramatically

This book should be equally interesting to laymen and those of the medical profession

It should be a further means of keeping "polio" before the American public until it is conquered

JOHN A. MONFORT

Synopsis of Pediatrics By John Zahorsky, M D, assisted by T S Zahorsky, M D Fifth edition Duodecimo of 449 pages, illustrated St Louis, C V Mosby Co, 1948 Cloth, $5 50

This must have been a very timely book in the days of Tr Fern Chloride and Ichthyol ointment Both of these remedies are strongly recommended by the authors Empyema is still being treated by thoracotomy and "a mortality of 25 per cent to 30 per cent is to be expected" The modern treatment of empyema by aspiration and penicillin injections is not even mentioned We are told by the publisher that this is a new book The chapter on asthma is equally amateurish if not misleading in its symptomatology

After perusing some of the more representative chapters, the reviewer is forced to the conclusion that this book is quite obsolete It is not fair to offer this to the student of medicine as a modern work

HARRY APFEL

Recent Advances in Anaesthesia and Analgesia (Including Oxygen Therapy) By C Langton Hewer, M B (Eng) Sixth edition Duodecimo of 380 pages, illustrated Philadelphia, Blakiston Co, 1948 Cloth, $6 00

In this small volume an attempt is made to embrace the whole field of anesthesiology which, of course, makes each part of the book inadequate because of its too wide scope

There are chapters on shock, cardiac massage, methods of nerve blocking, as well as others on oxygen therapy and resuscitation Each of these, actually containing only an occasional point is insufficient by itself However, the work is well illustrated, and some of the line drawings are illuminative

This book could serve as an introduction to the field of anesthesiology F PAUL ANSBRO

Detailed Atlas of the Head and Neck. By Raymond C Truex, M S, and Carl E. Kellner Folio of 162 pages, illustrated. New York, Oxford University Press, 1948 Cloth, $15

This atlas is the culmination of many years of diligent and careful dissections by Professor Truex, portrayed by the artist, Carl E Kellner, whose reproductions are almost "lifelike" We remember well the difficulties we had with our studies in anatomy and with our dissections, so we are indeed in a position to appreciate first hand the serial dissections and their artistic reproductions in this book. Those of us who are particularly interested in the anatomy of the head and neck will indeed enjoy a refresher course by the study and the much needed reference to this volume The head and neck surgeon can profit well by a study of the detailed dissections of the area which he is about to explore surgically We were helped materially by the fact that each structure was carefully identified with the naming of these structures directly on the illustrations which were beautifully done in color An atlas of this type should be in every hospital and every doctor's library SAMUEL ZWERLING

Pediatric Nursing By Gladys S Benz, R.N Octavo of 638 pages, illustrated. St Louis, C V Mosby Co, 1948 Cloth, $4 00

This is more than a book on nursing It is a reference work on the care of children at home as well as at the hospital It contains valuable information on sex education and a detailed discussion on entertainment for children

Ample space is devoted to the prevention and care of communicable diseases This book is well fitted for advanced study The book is well written, but it also contains superfluous material, e g, 101 pages are devoted to the bibliography on relevant subjects It is also profusely illustrated

HARRY APFEL

The Clinical Management of Varicose Veins By David Woolfolk Barrow, M D Octavo of 155 pages, illustrated New York, Paul B Hoeber, 1948 Cloth, $5 00

This well-written, short survey of the treatment of varicose veins and their allied complications can easily be read with sustained interest at one sitting

Controversial questions are eliminated and the modern concepts presented Numerous photographs and diagrammatic representations make reading matter readily understandable In extensive varicosities and in complicated conditions, high saphenous ligations, with stripping, is the treatment recommended as decreasing the incidence of recurrence The book is highly recommended

STANDARD PHARMACEUTICAL CO., INC., 1123 Broadway, New York

Manufacturers of NUCARPON ® Compound Charcoal Tablets for Intestinal Dysfunction

[Continued from page 1608]

nancy, to the first grade of school, the thousand and one questions parents ask a pediatrician have been intelligently answered

The many photographs and drawings aid the new parent in bathing, feeding, and handling the baby

The section reserved for records of the child's illnesses, date of injection, vaccination, growth charts, plus the pages where the first words spoken are recorded and dated and the various incidents of development set down, make the book a personal history up to the sixth year A most complete book!

JOHN A MONFORT

Therapeutisches Taschenbuch für Arzte und Studierende Edited by Dr G Ruepp Contributors, Prof W Burkhardt, Prof M Francillon, Dr E Hafter, *et al* Sextodecimo of 394 pages Bern, Switzerland, Medizinischer Verlag Hans Huber 1948 Cloth, 12 Sw fr

This is a small handbook of therapy compiled by a number of Swiss physicians The information contained is generally accurate but sketchy There is little in it to interest American doctors or students It is doubtful that a book of this sort would serve a useful purpose in any country except as a preparation for a most elementary examination

MILTON PLOTZ

Bailey's Text-Book of Histology Revised by Philip E Smith, Ph D , and Wilfred N Copenhaver, Ph.D Twelfth edition Octavo of 781 pages illustrated Baltimore, Williams & Wilkins Co , 1948 Cloth, $7 00

The twelfth edition has been revised by the above authors with many new illustrations and microphotographs and should prove valuable to students Several chapters have been revised since the beginning, and the first few editions have been brought up to date The authors should be congratulated for their contribution to one of the best histology books

NATHAN REIBSTEIN

Preoperative and Postoperative Care of Surgical Patients. By Hugh C Ilgenfritz, M D Octavo of 898 pages, illustrated St Louis, C V Mosby Co , 1948 Cloth, $10

Much has been written on pre- and postoperative treatment during recent years The discriminating reader has at times been obliged to exercise great diligence in separating the wheat from the chaff Dr Ilgenfritz has been evidently quite aware of the need for presenting his subject in a way that is clear, easily applicable, and devoid of elements of controversy His discussion of fluid and electrolyte balance is presented with a simplicity akin to finality, not often encountered The factors presented by the very young and the very old patient are handled in a way that leaves little unsaid that is worthwhile

The book is well written, thoroughly complete, and yet devoid of unnecessary, space-taking material

ANTHONY F SAVA

Bronchiogenic Carcinoma and Adenoma. With a Chapter on Mediastinal Tumors By B N Fried, M D Octavo of 306 pages, illustrated Baltimore, Williams & Wilkins Co , 1948 Cloth, $6 00

Dr Fried has written an admirable monograph on bronchiogenic carcinoma and adenoma with a chapter on mediastinal tumors The literature is intelligently summarized, and Dr Fried's personal observations are skillfully added to make a readable account which should prove valuable to every clinician The reviewer hopes that the chapter on the mediastinum will be expanded in future editions

MILTON PLOTZ

Medical Writing The Technic and the Art. By Morris Fishbein, M D with the assistance of Jewel F Whelan Second edition Octavo of 292 pages, illustrated Philadelphia, Blakiston Co , 1948 Cloth, $4 00

Probably Dr Fishbein has read more medical articles than any one else This opportunity constructively to criticize and so to advise has been added to an innate ability and much experience in his own writing This book gives useful advice from plain grammar and the use of the comma to collection of material and formation of the paper, with its final revision This book should be at the right hand of every aspiring, and other medical writer

WALTER D LUDLUM, SR.

Microbiology and Pathology By Charles F Carter, M D Fourth edition Octavo of 845 pages, illustrated. St Louis, C V Mosby Co , 1948 Cloth, $5 00

For nurses who need a short practical presentation of the fundamentals of bacteriology and pathology, this should continue to be a popular book. The plates and diagrams are generally relevant and helpful

ANDREW M BABEY

Essentials of Pathology By Lawrence W Smith, M D , and Edwin S Gault, M D Third edition Quarto of 764 pages, illustrated. Philadelphia, Blakiston Co , 1948 Cloth, $12

In the third edition of the *Essentials of Pathology* by Smith and Gault, the authors have executed an admirable improvement over the previous editions The material is exceptionally well selected and organized and very comprehensively and completely covered. The reading is easy, smooth, and attractive (a very important factor for the student) The classifications are orthodox, rational, and understandable for student and practitioner alike Both gross and microscopic illustrations are unusually clear and to the point From a general point of view, this book now takes its place among the best in pathology and should unquestionably find its place on every shelf of medical works

MAX LEDERER

Direct Electrocardiography of the Human Heart and Intrathoracic Electrocardiography By Franz M Groedel, M D , and Paul R Borchardt, M D Octavo of 224 pages, illustrated New York, Brooklyn Medical Press, 1948 Cloth, $9 00

Groedel and Borchardt have in this small volume compiled the results of their electrocardiographic observations on the hearts of some hundred or more patients on whom pneumonolysis was performed There is an exhaustive study of direct and intrathoracic electrocardiography under the given conditions While there is little here to interest the clinician, there is much that will be of importance to physiologists and electrocardiographers

MILTON PLOTZ

The Medical Clinics of North America. Boston Number September, 1948 Octavo Illustrated Philadelphia, W B Saunders Co , 1948 Published bimonthly (six numbers a year) Cloth, $16 net, paper, $12 net

The *Medical Clinics* are generally so helpful and good that new volumes need no comment in respect of this However often, a volume turns out to be especially outstanding as is this from Boston

The care of paralyzed patients, metabolic acidosis and alkalosis, urinary calculi, migraine, arthritis, and protruded intervertebral disks are articles which ought to be read by every medical man

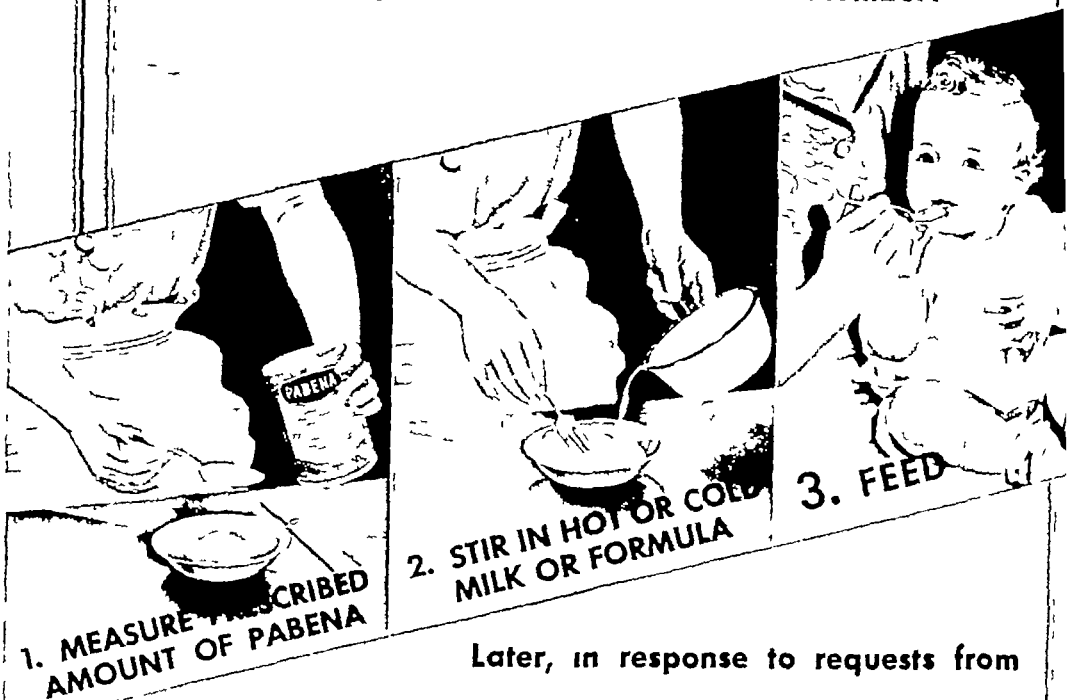
Announcing....

The availability of Synthetic Vitamin A 'WARNER' CAPSULES Eliminating fishy odor and taste

WILLIAM R WARNER & CO, INC takes pride in announcing the synthesis of VITAMIN A and its availability to the medical profession for therapeutic use

Synthetic Vitamin A 'Warner' is identical structurally, chemically, pharmacologically and physiologically with natural vitamin A

Synthetic Vitamin A 'Warner' (Synthetic Vitamin A Acetate) is more stable than natural vitamin A, thus minimizing deteriorative losses or destructive losses in the gastrointestinal tract. Synthetic Vitamin A Acetate 'Warner' is devoid of the fishy taste or odor so often found in natural vitamin A preparations



The high stability of *Synthetic Vitamin A 'Warner'* assures greater available quantities for absorption and assimilation Elimination of fishy odor and taste assures excellent tolerance by patients who are spared fishy aftertaste and fishy eructations

Synthetic Vitamin A 'Warner' is indicated in all conditions where vitamin A therapy is required

Synthetic Vitamin A 'Warner' (Synthetic Vitamin A Acetate), is available in packages of 24 sanitaped capsules, 25,000 units each

WILLIAM R. WARNER & CO., INC
NEW YORK ST LOUIS

Remember— in 1932 we brought out Pablum?* Embodying a new concept of cereal nutrition, easy of preparation, nonwasteful, forerunner of present day widely practised principles of food fortification—remember?

Later, in response to requests from physicians, we went a step further in Pabena,* similar in nutritional and convenient features to its father-product, Pablum, different in flavor because of its oatmeal base. If our pioneer work and ethical policy meet with your approbation, remember, please, to specify Pablum and Pabena.

*"Pablum" and "Pabena are the registered trademarks of Mead Johnson & Company for these vitamin and mineral-enriched precooked cereal foods

Mead Johnson & Company, Evansville, Indiana, U.S.A.

CAMP SCIENTIFIC PRENATAL SUPPORTS

Designs developed over many years, in full consultation with obstetricians, insure ample support for the abdominal musculature, pelvic girdle and lumbar spine without constriction at any point. All Camp Supports are accurately fitted about the pelvis. Thus the uterus is maintained in better position, the abdominal muscles and fasciae are conserved and there is support for the relaxed pelvic joints. The patient is assisted in maintaining better balance in the course of the postural changes of pregnancy. Physicians may rely on the Camp-trained fitter for precise execution of all instructions.

If you do not have a copy of the Camp "Reference Book for Physicians and Surgeons", it will be sent on request.

THIS EMBLEM is displayed only by reliable merchants in your community Camp Scientific Supports are never sold by door to-door canvassers Prices are based on intrinsic value Regular technical and ethical training of Camp fitters insures precise and conscientious attention to your recommendations.

These picture-words represent a primitive classification of urines used by early Babylonian and Egyptian physicians.

centuries to perfect seconds to perform

When Sumerian and Babylonian physicians, *circa* 4000 B C, noted the varying colors and constitutions of the "water of the phallus," they were probably not the first uroscopists in history They were assuredly not the last, for fifty-odd centuries were to elapse before Fehling's first paper on the copper reduction test for urine-sugar appeared in 1848

But centuries to perfect diagnostic procedures are condensed into seconds to perform the reliable *Clinitest*® method for urine-sugar levels From start to finish, the test takes less than a minute This tablet method is simplicity itself readily learned by every diabetic patient External heating is uniquely eliminated by the *Clinitest* procedure Routine test interpretation is made easy

ESTIVIN

Intraocular means of treating HAY FEVER

Prompt, safe symptomatic relief of the distressing hay fever symptoms—sneezing, nasal discharge, eye itching, lacrimation, etc —is effectively secured by Estivin

One drop in each eye upon arising, one before breakfast, and one after breakfast, will usually keep the sufferer comfortable well into the morning Estivin does not cause drowsiness, or depression, thus permitting application whenever indicated

if she is one

of your patients...

The farm housewife whose work is truly never done may find that the distressing symptoms of the climacteric make the smallest chore an arduous project She depends on your help to resume normal efficiency in the performance of her daily tasks as well as to maintain a positive outlook during this trying period

"Premarin" *offers a solution Many thousand physicians prescribe this naturally-occurring oral estrogen because*

1 *Prompt symptomatic improvement usually follows therapy*

2 *Untoward side-effects are seldom noted*

3 *The sense of well-being so frequently imparted tends to quickly restore the patient s confidence and normal efficiency*

4 *This ' Plus (the sense of well-being enjoyed by the patient) is conducive to a highly satisfactory patient-doctor relationship*

5 *Four potencies permit flexibility of dosage 2 5 mg 1.25 mg 0 625 mg , and 0 3 mg tablets also in liquid form, 0 625 mg in each 4 cc (1 teaspoonful)*

Ayerst

While sodium estrone sulfate is the principal estrogen in Premarin other equine estrogens estradiol equilin equilenin hippulin are probably also present in varying amounts as water soluble conjugates

LEG ULCERS

the DAXALAN-DOME-PASTE BANDAGE TECHNIQUE

AS INTRODUCED BY DR WILLIAM M. COOPER Director Department of Peripheral Vascular Diseases—New York Polyclinic Medical School and Hospital.

This technique is based on a 3 point program—

1. Reduction of dermatitis with wet dressings of DOMEBORO TABS *(BUROW S SOLUTION)*
2. Combat local infection and stimulate healing with thick application of DAXALAN in the center of the ulcer and surrounding areas.
3. Overcome venous insufficiency stasis and edema by wrapping DOME PASTE BANDAGE around the entire leg to supply compression.

DOCTOR! You may now prescribe SOOTHING Modernized Simplified Fresh and Stable BUROW'S SOLUTION 120 in four forms DOMEBORO Tablets Packets Powder Ointment

When sedation is desired *Nitranitol with Phenobarbital* (¼ gr. Phenobarbital combined with ½ gr. mannitol hexanitrate.)

For extra protection against hazards of capillary fragility *Nitranitol with Phenobarbital and Rutin.* (Combines Rutin 20 mg. with above formula.)

attacking arthritis

at the G-I level

With so many arthritics exhibiting evidences of constipation and hypofunction of the gallbladder, liver and kidneys—it is today generally conceded that "proper handling of the gastro-intestinal tract may in some cases be the most important factor in successful management."* The Occy-Crystine formula is frequently used with benefit—to provide effective, non-irritant cathartic and cholagogic action; it is also sulfur-bearing

Composition Occy-Crystine is a hypertonic solution of pH 8 4, made up of the following active ingredients—sodium thiosulfate and magnesium sulfate, to which the sulfates of potassium and calcium are added in small amounts, contributing to the maintenance of solubility

*Nuzum, F R.: In Diseases of the Digestive System ed by S. A. Portis Lea & Febiger 1944.

Findings from the Saratoga Spa records*

CARBON DIOXIDE BATHS in circulatory diseases

The physiological observations of the influence of carbon dioxide baths show a decrease in the pulse rate, an increase in the pulse pressure dependent mainly on a drop of the diastolic pressure, a better emptying of the venous blood vessels, a hyperemia with increased capillary circulation, a slightly elevated minute volume output of the heart, an increase in respiration and the elimination of large quantities of the carbon dioxide through the lungs

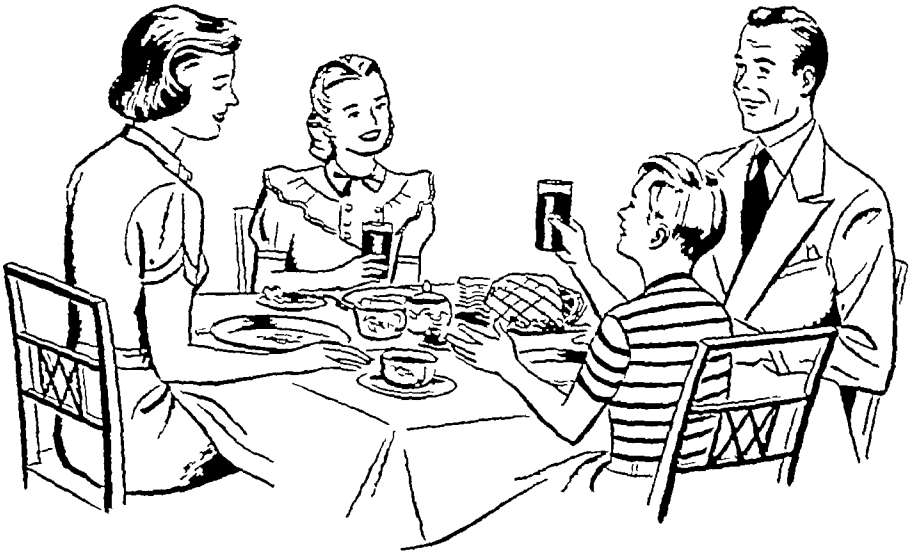
In evaluating the results of this treatment for patients with circulatory disorders there is no ideal test of cardiac function and in these patients the ability to walk or exercise without the production of symptoms is used in judging their clinical gain In addition, in the patients with coronary disease suffering from anginal attacks, it is striking to note the decrease in the frequency and severity of these attacks In some patients they will disappear completely

Objective changes as seen in physical examination and in the studies of pulse rate, blood pressure, roentgen ray findings, electrocardiographic tracings, and vital capacity are noted in many patients

The clinical improvement of many patients undergoing treatment, their continued well being after their return home and their desire periodically to return for further treatment all indicate that the carbon dioxide bath has its place in the treatment of disorders of the circulation

As printed in International Clinics, Vol. 1 page 199 March 1937

The SARATOGA SPA



'Physician Give Heed to Thine Own Health"

Many physicians have come to the Spa for the same kind of treatments that have helped their patients here After a restorative "cure" at the Spa, you, too, will return to your practice refreshed—revitalized—ready for the busy days that lie ahead

For professional publications of the Spa, and physician s sample carton of bottled waters with their analyses, write W S McClellan, M D., Medical Director, Saratoga Spa, 155 Saratoga Springs, New York.

Listed by the Committee on American Health Resorts of the American Medical Association

THE EMPIRE STATE'S CONTRIBUTION TO THE MEDICAL PROFESSION

WHEN THE DIET

Needs Supplementation

Comparison of the accompanying two columns of nutritional values clearly shows why Ovaltine in milk has been so widely accepted as a highly effective *multiple dietary food supplement*

Column A lists the National Research Council's Recommended Daily Dietary Allowances for each *100 calorie portion* in the diet of a 154 pound man of sedentary occupation Column B lists the amounts of the same nutrients provided by a *100 calorie portion* of Ovaltine in milk

	A N. R. C. Diet	B Ovaltine in Milk*
CALORIES	100	100
CALCIUM	40 mg	166 mg
IRON	0 5 mg	1 8 mg
PHOSPHORUS	60 mg	139 mg
VITAMIN A	208 I.U.	444 I.U.
THIAMINE	0 05 mg	0 17 mg
RIBOFLAVIN	0 08 mg	0 30 mg
NIACIN	0 5 mg	1 0 mg
ASCORBIC ACID	3 1 mg	4 4 mg
VITAMIN D		62 I.U.
PROTEIN	2 9 Gm	4.7 Gm

The easy digestibility and appealing flavor of Ovaltine in milk enhance its value as a dietary supplement Chocolate Flavored Ovaltine is especially liked by children

*Based on average reported values for milk. Three servings of Ovaltine each made of 3½ oz. of Ovaltine and 8 fl oz. of whole milk, the daily dosage recommended for diet supplementation, provide 676 calories.

Two kinds, Plain and Chocolate Flavored Serving for serving, they are virtually identical in nutritional content

Why MENAGEN®?

oral estrogens, *Parke-Davis*

evenly maintained...
easily regulated
therapeutic levels

In management of the menopause and other estrogen deficient states MENAGEN capsules provide the benefits of natural hormone therapy supplemented by additional unique advantages Containing a highly refined concentrate of estrogenic factors, the attractive flame-colored, soft gelatin capsules of MENAGEN are free from unpleasant taste and do not impart an objectionable odor to the patient s breath or perspiration

Doses of one to two capsules daily as required afford an evenly maintained and easily regulated therapeutic level Well tolerated and clinically effective, MENAGEN produces a sense of well-being because of its natural origin.

Each MENAGEN capsule contains the equivalent of 10,000 International Units of ketohydroxyestratriene Bottles of 100 and 1000 capsules

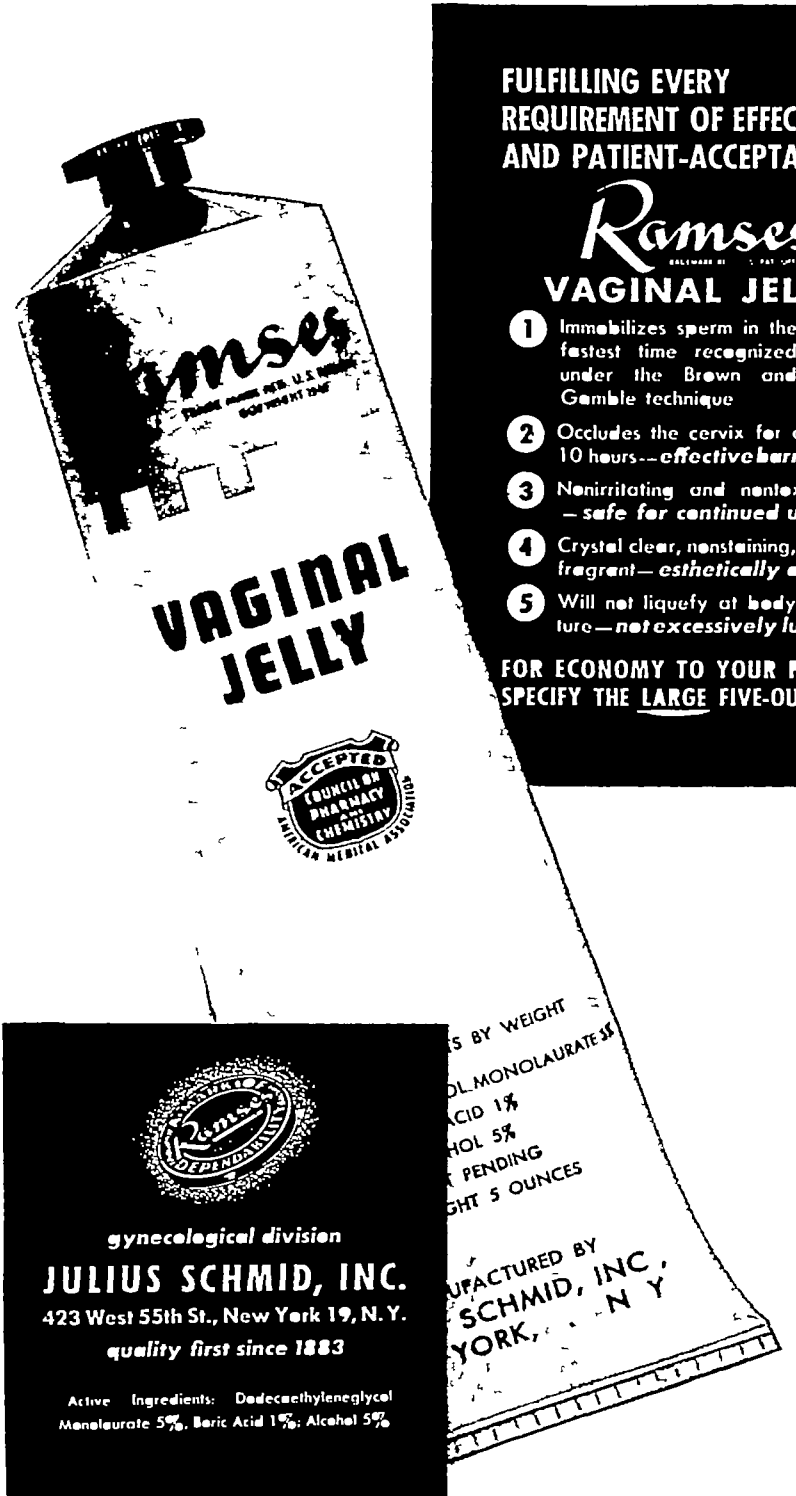
PRECALCIN

THROUGHOUT PREGNANCY AND LACTATION

MAINTAIN THE PATIENT'S VITAMIN-MINERAL BALANCE

PRECALCIN supplies all of the essential vitamins in association with readily assimilable calcium, phosphorus, and iron in an easy-to-swallow, colorful gelatin capsule (dry powder "fill")

Although they supply ample amounts of Vitamins A and D, PRECALCIN* Capsules are entirely free of fishy taste or odor They are acceptable even to the most fastidious patient



PRECALCIN is offered for use under the guidance of the physician only It is never advertised to consumers

PRECALCIN is supplied in bottles of 100 capsules and is available to patients through all prescription pharmacies

Samples and literature to physicians on request

INOSITOL

CSC

A MEMBER OF THE VITAMIN B COMPLEX OF GREAT THERAPEUTIC PROMISE

THE availability of inositol, a member of the vitamin B complex, follows many years of intensive laboratory and clinical investigation In the experimental animal inositol has been shown to be intimately concerned with fat and lipoid metabolism It exerts a distinct lipotropic action on the liver and is capable of counteracting the influence of metabolic aberrations or of a disturbed dietary known to induce lipoid degeneration Inositol also has been shown to reduce the severity of or prevent the development of atherosclerosis in animals fed a high cholesterol diet

While the clinical applicability of inositol is not clearly defined at this writing, most of the investigators who have worked with this substance are unanimous in the thought that it holds great promise in the treatment of degenerative arterial processes, many hepatic disorders, and certain metabolic diseases It has been used in the treatment of cirrhosis of the liver, xanthomatous cutaneous lesions, atheromatous disease, psoriasis, and hypercholesteremia

Inositol-C.S C. is available in 0 5 Gm capsulettes (capsule shaped tablets) in bottles of 100 A complete review of the literature on inositol and dosage recommendations arising therefrom are available

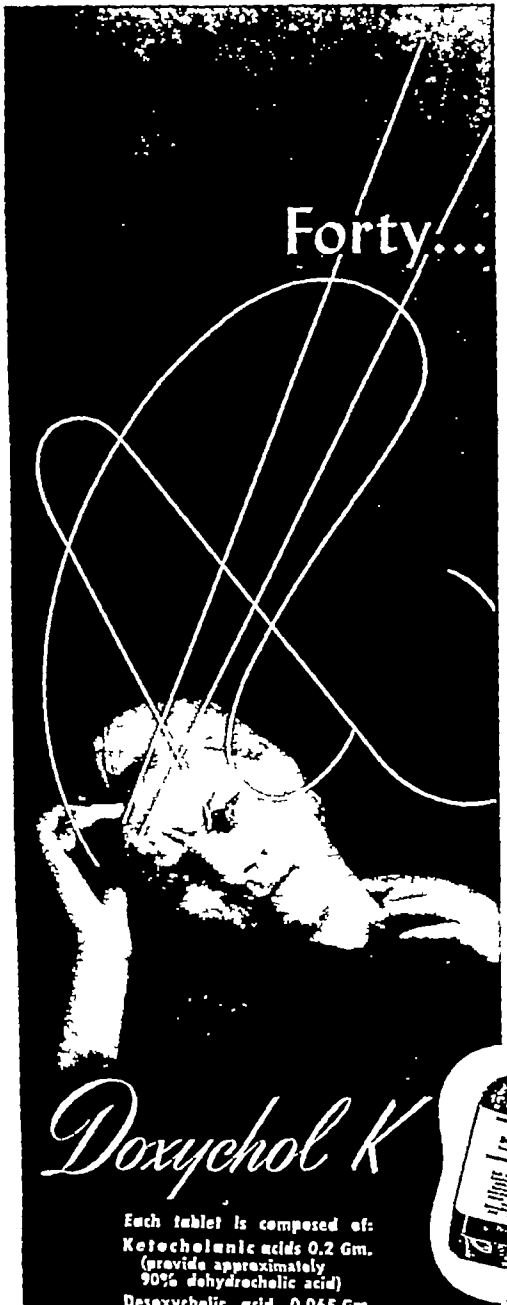
EVER X-RAY A WHISKEY?

OF COURSE, whiskies can't be X-rayed, but they *can* be analyzed Analysis reveals why today so many physicians recommend (of) blended whiskies to their patients when whiskey is indicated

For neutral spirit blends contain few congeners, such as fusel oil, tannins, aldehydes, esters, furfurals, acids, etc That means neutral spirit blends are not only light but mild, too What's more, they are usually low in alcoholic content

One of America's leading whiskies of this type is Carstairs White Seal Extremely low in congeneric content, it is blended with care by master distillers unmatched for skill and experience And, though high quality, it is surprisingly *low in price*

Whenever whiskey is indicated, may we suggest that you recommend that superb blend—Carstairs White Seal whiskey—to *your* patients?



The Medical Man who Cares says:

Fat, and— Fair Treatment

It has been said that the gallbladder is seldom anatomically normal in middle age; and also that the woman over 40 is apt to attribute any complaint to either the menopause or her gallbladder. There is perhaps some justification for the latter lay-diagnosis, since bile tract abnormality is 2½ to 3 times as common in women as in men.

Treatment based on physiological principles, it has been shown, will improve three out of four cases. The well known, simple regime is based on these essentials

1 Gallbladder emptying is stimulated by fat, especially uncooked fat such as butter and cream.

2 Utilization of the fat is aided by giving Doxychol K*, its desoxycholic acid content is noted for efficient transport of fatty compounds across the intestinal mucosa.

3 Doxychol K also markedly increases the flow of hepatic bile to further improve drainage of the biliary tract.

Medicine in the News

The recently terminated meeting of the House of Delegates of the A.M.A. as reported in the press for popular information left much to be desired. Apparently, according to the press, the Association is still "reactionary," lacks even now a program for improved medical care, is unrepresentative of its physician membership, is dilatory and domineering. One ponders these press reports with some concern. If the A.M.A. is really like that, from what source has the admittedly excellent medical service in this nation stemmed? What agency has raised medical education to its present high standards? What agency has been responsible for improved hospitals, for better training of doctors as interns and residents? What agency, then, has been responsible for the suppression of quackery and the elimination of fraudulent medical advertising? Are these things "reactionary," for example? Of no value to the public? Of no consequence to the sick?

We are not informed in the press reports whence these real values emanated. They are so much accepted as a matter of course that in these busy days no one bothers himself to consider that, without these real values, built up over the years patiently and enduringly, better distribution of good medical service on whatever basis would be impossible, because it would not exist. Even so relatively recent a development as voluntary hospital and medical care insurance would be a farce if the hospitals and the doctors had not been able, through long years of preparation, to implement such insurance by the highest attainable skills.

As pointed out by the A.M.A.,

> The voluntary hospital and medical care insurance development in the United States, the trustees declared, "has been the most rapidly growing insurance project in the history of the country.
>
> "The movement," they pointed out, "started slowly. At the end of the first seven years of voluntary hospital insurance under the Blue Cross, only 2,870,000 subscribers were enrolled. Now, after about sixteen years, there are 32,500,000 enrolled in the Blue Cross and over 20,000,000 enrolled in industrial and commercial types of plans, and all three types are continuing their rapid growth.
>
> "For the protection of the public the American Medical Association has aided in the devel-

comfort

Basic need is met when 'Surfacaine' (Cyclomethycaine, Lilly) is applied to damaged, irritated, or diseased skin and to rectal or genito-urinary membranes. Sustaining comfort is provided promptly and thoroughly, yet safely, with this new type of surface anesthetic.

Relief from pain usually lasts up to eight hours with 'Surfacaine.' However, it may be reapplied freely at shorter intervals, if necessary, and over extensive areas. Unlike topical analgesics whose value is sharply limited by high toxicity, 'Surfacaine' may be used liberally

It is soothing to the tender skin of infants with diaper rash, to burns that are superficial or deep, to painful hemorrhoids, and to itching skin conditions.

Readily available as:

Ointment 'Surfacaine,' 1 percent, in 1-ounce tubes with removable, perforated rectal tips and in 1 pound and 5-pound jars

Cream 'Surfacaine,' 0.5 percent, in 1-ounce tubes and in 1 pound and 5-pound jars

Lotion 'Surfacaine,' 0.5 percent, in 4 ounce and 1-pint bottles

Suppositories 'Surfacaine,' 10 mg., in packages of 12 and 100

Suppositories 'Surfacaine,' 10 mg., and Sulfadiazine, 325 mg., in packages of 12

Suppositories 'Surfacaine,' 10 mg., and Zinc Oxide, 250 mg., in packages of 12

Accident Prevention

While physicians and ancillary services labor unceasingly to improve the means for prevention and treatment of disease, accidental death and destruction in the home, on the streets and highways, in manufacturing plants, in the air, and in the waters continue to take their appalling toll of human life Says the *Illinois Medical Journal*,[1]

> We are reminded daily of the death toll and disability resulting from accidents The 100,000 annual deaths gives it third place on our mortality tables and, were a cancer cure to be found tomorrow, accidents would move overnight into second place This is an ironical situation considering the advancements we have made in the prevention and treatment of disease during the last decade
>
> The injured have received, from a statistical standpoint, too little attention and, by neglecting this aspect, the problem has been minimized. By using fatalities as the measuring stick the loss of time and efficiency produced by temporary and permanent physical disability is overlooked This is evident when it is considered that accidents caused the death of 100,000, but at the same time over ten million individuals were injured
>
> The treatment of injuries is a major part of every physician's practice Many advancements have been made to lower the death rate and minimize disability and deformity Prevention, however, is another matter, and until recently physicians were prone to accept this phase as being out of their realm They readily admit that if a man dies in an automobile mishap he is just as dead as his neighbor who succumbs to pneumonia The youngster who developed paralysis after falling from a ladder fares no better than his playmate with a similar handicap resulting from polio In other words, the outcome is often the same whether we sustain an accident or fall prey to disease The difference lies in the etiology, but there is no reason why the field should be neglected by the medical profession because bacteria, degeneration, or hormones are not involved
>
> Preventing disease is not new to the physician, and there is reason to believe that some of the same procedures can be followed in the prevention of accidents It means a thorough epidemiologic study of these mishaps Preventive measures have been in progress for several years to curtail traffic and industrial accidents The effects are noticeable in spite of statistics to the contrary This pertains particularly to automobile accidents, as the mortality rate has been rather constant for several years even though there has been a marked increase in traffic and passenger miles The worker also has benefited, and studies now show that the number of fatalities among our employed is almost twice as great off the job as on

Off the job accidents present a vastly more serious problem in control than those subject to in-plant regulation Consider the lack of uniformity of motor traffic laws, the still somewhat farcical "examinations" for an individual's fitness for driving, the increasing number of old people who drive, for example, and the reckless individual of any age who drives while under the influence of alcohol

> But the prevention of home accidents has lagged behind, and it is here that epidemiologic studies are needed the most Thirty-five per cent of all deaths from tragedies of this nature occur in or about the house—a figure which would give it ninth place among all causes of death. Furthermore, of the 10,520,000 who were injured in 1947, 5,200,000 were injured at home It has been estimated also that 140,000 of the latter were left with a permanent defect. The majority of these mishaps resulted from falls, burns, suffocation, poisonous gas, poison, and fire arms
>
> The home is in the domain of the physician, and it is here that the "when, where, how, and who" data can be collected to formulate preventive measures We dropped the notion years ago that disease and infection were due to an evil, some misfortune, bad luck, or a mistake of nature, and the same viewpoint must be taken in respect to accidents Less pity and more etiology will go a long way in teaching safety This aspect of life deserves as much attention as vaccination, quarantine, cleanliness, antisepsis, diet, and sleep Who are better qualified than the family physician and community hospital to start a project of this nature?

Occupational motor vehicle accidents are a serious factor also How serious and expensive anyone knows who carries automobile insurance Says the *Statistical Bul-*

[1] Illinois M. J. 95 257 (May) 1949

opment of standards for voluntary insurance plans The Association is conducting a campaign to educate both the public and the profession on the value of voluntary medical care plans

"The Association has recognized the desirability of a national voluntary enrollment agency for the nonprofit plans to facilitate interchange and enrollment of companies with national payrolls It is believed that at least 80,000,000 will be enrolled within a reasonable time in voluntary hospital and medical care plans When we add this number to the 24,000,000 now receiving their medical care in whole or in part from the government, the industrial workers covered by established health plans, and the approximately 5,000,000 indigent, it will be seen that a greater portion of the population will be provided for than by any other means suggested "

Of the establishment of local public health units the trustees said

"Prevention of disease at the source will decrease the need for medical care There are bills now in Congress to extend Federal aid to communities needing it for this purpose We support legislation which will permit aid to local communities

"There is a shortage of qualified public health officials and the public health schools are graduating too few students The reasons for this are largely monetary and political "

The relationship of county and state medical societies to the A M A., as interpreted in at least one editorial, is confusing [1] As a matter of fact, much of the pioneering study and experience with respect to the improvement of good medical service distribution, as any doctor should know, has been initiated and carried out on the local level A little thought on the subject shows why Conditions are so different, real needs so various in this country, that only by local experiment, by trial-and-error procedure can workable methods be arrived at by representatives of the medical profession, agencies of government, and the various sections of the public such as industry, farming, labor, and the like Procedure which is acceptable in one area fails sometimes to produce the same result in another Thus difficulties increase as one goes from county to state level and from there to national considerations

It should not be forgotten also that responsible leadership in farm organizations, in labor groups, and in many industries is a matter of relatively recent development and even now is less than ideal

Government, too, cannot be counted on to exhibit that nonpolitical responsibility and impartiality at all times which is conducive to orderly development of plans for the better distribution of good medical service This is somewhat less disastrous at the local level where the citizens can see what is happening

With these considerations in mind, the reasons for the most successful experimentation at the lower levels becomes clear Such recommendations as the county societies make are carried by their delegates to the state societies and from there if thought practical to the national Association Obviously, what may be entirely workable at any given county level may not work at all or not too well in another environment However, most of the progress originates on the local level within the framework of the *principles* established at the higher policy levels

Perhaps it is not possible, concededly it is difficult for news stories of recent happenings to convey a proper (in the sense of comprehensive) regard for the sequential background of evolutionary development

People and institutions are largely judged by the *last* things they have or have not done, regardless of the context of history, from which their last actions are divorced by journalistic limitations of time, space, and perhaps an unfamiliarity on the part of writers with the background

Certainly, progress is being made by hardworking doctor-delegates and their leaders consistent with the degree of responsibility and liability involved when human lives and health are concerned Such doctors infrequently wear the silk hat, morning coat, and striped pants of formal diplomacy, they make mistakes like other humans, but they do produce the best possible medical service, they *are* the A.M.A. and, given time and public cooperation, will solve the vexing problems in keeping with the medical needs of this industrial day

[1] New York Times June 11 1949

and on trips, sometimes to unfamiliar places If the frightful accident toll can be cut down by education of the public, something will have been gained not only in the preservation of useful lives ut so in a lessening of avoidable de an upon overcrowded hospital and h medical facilities

---

Current Editorial Comment

So We Gave Him Penicillin. For many years we have been saddened by seeing medicine outreach itself About fifty years ago, all congenital dislocations of the hip were to be cured by Dr Lorenz's bloodless method The millionaire's daughter that he was brought here to cure, with tremendous fanfare of newspaper publicity, is still as badly off as she ever was Next we had 606 One injection, and syphilis had lost its terrors That wasn't quite true, either Then two men from Australia arrived to tell us how to cure cases of spastic cerebral paralysis by operations on the sympathetic nervous system Hunter is dead Where Royle is we don't know

The sulfa drugs invaded us A wonderful advance, to be sure, but what about their crystallization in the kidneys, suppression of urine, and other complications?

Then came penicillin The antibiotic, the underground warrior against bacteria Suppose you can't make an immediate diagnosis, shoot the patient full of penicillin, and nine times out of ten you'll cure him Perhaps But what happens in the one case that you don't? We quote from a summary of a recent article [1]

> Symptoms were markedly altered by chemotherapy (for this we think should be read the combination of sulfa drugs and penicillin) in the following conditions (1) diverticulitis with cancer, (2) fibrosarcoma, (3) perinephritic abscess, (4) lung abscess, (4) acute cholecystitis, (6) subphrenic and subhepatic abscess, (7) mastoiditis, (8) empyema, and (9) osteomyelitis

The patient enters the hospital, evidently sick and with an alarming fever Well, of course, on a cursory examination, you can't make an exact diagnosis The Attending Surgeon can't be reached, so what can the House Officer or Resident do? Why, give him penicillin, of course Not an overwhelming dose, naturally, because he doesn't dare to, until the diagnosis has been made, but just enough to keep the temperature down and the bugs quiet, until the allwise Attending or the still more unfortunate Consultant comes along How can either of them possibly make a diagnosis? The temperature is down, the bacilli are hibernating All signs of danger are masked

Finally someone says, "How long is this patient going to stay here? No temperature No physical signs Discharge him"

Then, the penicillin having been stopped, he comes back, sick all over again And with the diagnosis, which has never been made, still more difficult because the symptoms have been masked, and the virulence of the bacteria lessened But they are still virulent And they eventually break out And when they do, penicillin is much less effective than it might have been, because it has already been used as birdshot instead of buckshot

Is it too much to ask of our ultra scientific hospitals that they make at least an attempt at diagnosis before they mask every presenting symptom by flooding the patient with an antibiotic? Is it too much to ask that the medical profession should not again be swept under by one of the tidal waves we have already outlined?

Doctors made diagnoses before they had the x-ray, the Wassermann reaction, the electrocardiogram They used their five senses and they used to think Remember?

[1] J.A.M.A. 138 645 (Oct. 30) 1948

letin of the Metropolitan Life Insurance Company,[2]

> Motor vehicle accidents rank among the leading causes of occupational fatalities, although their importance in this connection is frequently lost sight of because of the far larger role they play in nonoccupational injuries The number of men killed on the job by motor vehicles is, however, very considerable It is estimated that about 2,500 men lose their lives in accidents of this kind each year This number is equal to about eight per cent of all motor vehicle fatalities and to nearly 15 per cent of all deaths arising out of or in the course of employment
>
> In order to throw light on the circumstances surrounding occupational motor vehicle accidents, the Metropolitan Life Insurance Company has analyzed the death claim records of 363 men insured in its Industrial Department who died of such mishaps in the three-year period 1946–1948 As might be expected, a much larger proportion of the motor vehicle deaths of occupational origin than of other motor vehicle deaths occur among drivers and other occupants of vehicles The tabulation shows that somewhat more than three fifths of those killed were driving at the time of the accident Occupants of the vehicle other than the driver accounted for an additional one fifth of the total, an almost equal proportion were nonriders It should be noted that this study represents essentially an urban experience, inasmuch as the insured are heavily concentrated in the cities and the larger towns

Vacation hazards to watch include unsafe water and food supplies, ticks, snakes, the black widow spider, and mosquitoes, says the current issue of *Hygeia*, health magazine of the American Medical Association [3]

Look out for poison sumac, as well as poison ivy and oak

Cold foods that may be saved and served from day to day at wayside restaurants can be unsafe Intestinal diseases, including typhoid fever and dysentery, are carried by infected food, water, or milk Boiling of water, pasteurization of milk, and thorough cooking of meat are essential in avoiding these diseases Trichinosis should be guarded against by cooking pork thoroughly When in a strange place and doubtful as to the safety of food or drink always boil or sterilize it

Besides taking much of the fun out of vacation, ticks can transmit Rocky Mountain spotted fever—even in New England, according to Dr Silvers [3] Hardshelled species that can carry it are common throughout the country, and the disease has been reported from coast to coast The ticks attach themselves to human beings tramping through woods or fields Don't remove a tick with bare hands—use a needle or cotton saturated with alcohol, lighter fluid, or kerosene Advance protection by spotted fever vaccine is available.

People who vacation in country where the copperhead, rattler, or water moccasin lurk may need a special type of first aid kit containing antivenin A bite from a black widow spider, while not often fatal, can be extremely disabling This shiny "shoe button" spider may be recognized by red markings, usually including an hourglass on the under side Mosquitoes still carry malaria in a few spots in the southern United States

Those persons who are extremely susceptible to poison ivy, oak, or sumac can be desensitized by injections prior to vacation, Dr Silvers says Immediate thorough washing with soap and water and rinsing with a solution of ordinary baking soda will reduce and often prevent reaction to these plants

A little "brushing up" on first aid, especially on artificial respiration, may enable vacationists to save their own or friends' lives, he points out But, in an emergency, don't try to "play doctor" Use reliable first aid technics and call a doctor of medicine as quickly as possible

A good idea, too, is to consult a doctor well in advance of a vacation to be taken in out-of-the-way places He can give instruction in use of first aid equipment and advise whether immunization against disease hazards such as typhoid and tetanus is needed [3]

The physician has indeed an important role to play in accident prevention of all kinds He is in the most intimate contact with those who are going to vacation camps

SAFE, EFFECTIVE ANTIBIOTIC THERAPY IN MOUTH AND THROAT

Bacillus Brevis. From a culture of this soil organism tyrothricin is extracted, purified and dried.

LOZILLES®

(Lah-zeels)

TYROTHRICIN-PROPESIN LOZENGES

Potent Antibiotic Action:

The organisms most commonly responsible for acute oropharyngeal infections are extremely susceptible to the high salivary concentration of tyrothricin supplied by Lozilles

Non-toxic:

Tyrothricin is remarkable for its *lack of local toxicity* and no systemic side-effects result from its ingestion

Non-sensitizing:

The local use of tyrothricin, in contrast to topical penicillin, is remarkably free from sensitivity reactions

Prompt, Long-lasting Analgesia:

Propesin, a non-toxic, non-irritating local analgesic agent brings effective and *prolonged* relief to irritated or inflamed mucosal surfaces

Palatable:

Pleasant-tasting, Lozilles' mild citrus flavor assures patient cooperation at all ages

Each Lozille contains 2 *mg* of tyrothricin and 2 mg of propesin
Supplied in vials of 15 Lozilles

William A Brumfield, Jr, M D, Editor

BCG Vaccination Program in New York State

The development of a particular strain of bovine tubercle bacilli which had lost virulence was announced in 1908 by Calmette and Guerin Twelve years later, they reported that the culture of this strain was harmless to man Vaccine produced from this strain was used and became referred to as BCG Subsequent studies in vaccinated groups have reaffirmed the safety of the vaccine and produced evidence of significantly lowered morbidity and mortality rates for varying periods of time

The possibilities of incorporating this method of vaccination into the tuberculosis control program of the New York State Department of Health were explored carefully by the Advisory Committee on BCG Vaccination to the Medical Society of the State of New York and the New York State Department of Health It was decided to recommend the use of this vaccine in limited groups of the population A special laboratory was equipped within the Division of Laboratories and Research of the New York State Department of Health, and production of vaccine was begun

The use of BCG vaccine is recommended in groups that have not received a tuberculous infection (as shown by no reaction to tuberculin test) but are at increased risk of such infection These groups include those (1) with occupational exposure, such as nurses, medical students, and hospital personnel, (2) with high tuberculosis morbidity and mortality rates, and (3) with a known or potential exposure to tuberculosis, as in the household of tuberculous persons returning from a hospital stay BCG vaccine is not to be administered indiscriminately, because it can be of benefit only to those persons who have not been infected by the tubercle bacillus BCG vaccine has no value in the treatment of tuberculous disease

For the present, BCG vaccine is distributed on request to (1) local full-time health departments, (2) medical colleges and teaching hospitals, (3) superintendents of public tuberculosis hospitals and directors of tuberculosis clinics, and (4) additional hospitals and institutions with specially trained physicians who have been designated by the State Commissioner of Health to administer BCG vaccine

The State Department of Health is prepared to give consultation and advisory service to local agencies, but the details of the program are carried out by local personnel and facilities Assistance may be obtained in planning a program locally and arrangements may be made for instruction and demonstration in vaccination procedures

Local agencies participating in BCG vaccination activities include local full-time health departments, medical schools, nurses training schools, general hospitals, hospitals for the tuberculous, and tuberculosis clinics.

Data concerning vaccinated persons are assembled in the State Department of Health With the accumulation of information concerning observations following vaccination it will be possible to add to the knowledge available of the effectiveness of the vaccine and to learn more of the duration of its protective benefits

As of December 31, 1948, BCG vaccination programs have been started in seven medical schools in the State Twenty-one schools of nursing have begun offering BCG vaccination to their student nurse groups, and eight others have begun vaccination in those students affiliating with hospitals for the care of tuberculous patients Other groups included are contacts, hospital personnel, and other miscellaneous groups As part of a study to determine the practicability of use of vaccine in State mental hospitals and State schools, several groups of patients and employes have been vaccinated

There were 3,553 persons in various categories for whom records of BCG vaccination were available on December 31, 1948

The use of this vaccine does not take the place of or alter any of the long recognized methods of controlling tuberculosis, such as case-finding, medical care, and segregation However, BCG vaccination may play an increasingly important part in the total tuberculosis program

PRECANCEROUS AND CANCEROUS DERMATOSES OF THE SKIN

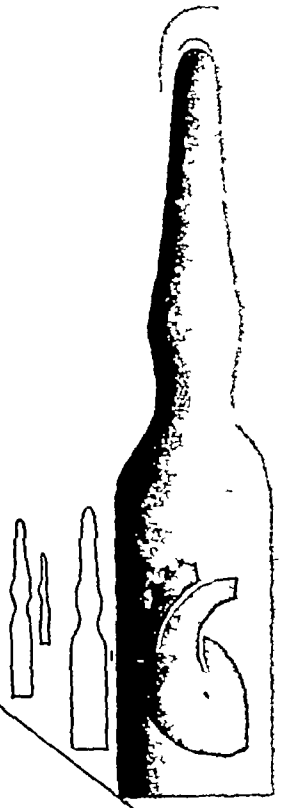
Precancerous Lesions of the Skin

GEORGE C ANDREWS, M D , and CHARLES F POST, M D , New York City

(From the Department of Dermatology, College of Physicians and Surgeons, Columbia University)

WITHIN recent years several excellent treatises have appeared concerning precancerous lesions and diseases of the skin [1–3] A simple reiteration of this material would prove superfluous, particularly when such a presentation is being made for members of the profession who are constantly dealing with these problems An attempt will be made, therefore, to emphasize recent contributions and newer forms of treatment

While the term precancerosis and the concept of the precancerous dermatoses have been attacked from many quarters, it would seem advisable to preserve a high degree of suspicion of possible malignancy in certain cutaneous diseases It is within our province to practice prevention and prophylaxis against malignancy in the known precancerous conditions In no other field of medicine can this be so readily accomplished, for the entire integument is subject to careful inspection by the physician and patient Cancer education will serve to reduce the incidence of cutaneous carcinomata caused by occupation or by chronic ulcers, cysts, and infected sinuses, where surgical measures and the administration of the sulfonamides and the antibiotics may bring about early removal of these potential sources of chronic irritation. With the increasing amount of cancer education the public is receiving, the responsibility of dermatologists is greatly increased



Actinic Dermatitis

Nowhere is this so well illustrated as in the prevention of cancer of the skin caused by exposure to excessive amounts of sunlight over a prolonged period Piers, in presenting data on sunlight and skin cancer in Kenya Colony, Africa, has divided the cutaneous changes associated with chronic actinic exposure into three types, (1) permanent suntan, composed mainly of dark-haired and brunette-skinned individuals in which group skin cancer seldom occurs, (2) farmer's skin with diffuse cutaneous changes in which the skin is yellow or sallow, thick and tough or atrophic, with coarsening of the skin and deepening of the lines and folds of the face and back of the neck, and (3) chronic solar dermatitis, in which there are epidermal lesions (desquamation, keratoses, permanent freckling, atrophy, and telangiectasia) superimposed on the changes seen in farmer's skin [4] Piers goes on to report the frequency on exposed parts of the body, chiefly the face and neck He concludes that " sunlight is the paramount factor in the causation of cutaneous carcinoma in Kenya " Surely, except for unnatural hazards such as x-ray exposure, some occupational exposure, and arsenical medication, the same conclusions apply throughout the United States

If, for any reason, we are called upon to treat blond, fair-skinned individuals, who have a tendency to premature aging of the skin, or those persons whose occupation submits them to the hazard of continued actinic exposure, we instruct these persons in the care of their skin These measures consist of (1) maintenance of good general health with sufficient food and rest, (2) careful hygiene of the skin and in some cases the application of skin lubricants, (3) protection against sunlight as much as possible by means of caps and hats, long sleeves and gloves, and occasionally sun-screen pastes or lotion, (4) warning against excessive sun bathing for any

Presented at the 143rd Annual Meeting of the Medical Society of the State of New York, Buffalo Section on Dermatology and Syphilology May 5 1949

a natural preference

A revealing test[1] recently was conducted on a group of cardiac patients in congestive failure, treated with intramuscular injections of different mercurial diuretics, the identities of which were unknown at the time to both patients and observers. The results showed that the majority clearly evinced a decided—and natural—preference for a diuretic agent that caused the least pain and discomfort—

MERCUHYDRIN®

Similarly, Gold *et al*[2] prefer MERCUHYDRIN in their routine treatment of the failing heart because "it is less irritant to the muscle and is less apt to produce pain"

MERCUHYDRIN is also preferred by the treating physician because of its dependability It is well tolerated systemically,[3,4] excellent water and salt diuresis is obtained,[1,4-6] and the diuretic response by intramuscular injection is the same as by intravenous injection.[1,4] With a systematic schedule of early and frequent administration producing controlled diuresis, MERCUHYDRIN aids greatly in prolonging the life, decreasing the invalidism and adding to the comfort of the cardiac patient. Symptoms of failure, such as peripheral edema, paroxysmal dyspnea or acute pulmonary edema, are prevented or minimized, and the distressing consequences of intermittent massive diuresis are obviated.

DOSAGE: MERCUHYDRIN 1 cc. or 2 cc. intramuscularly or intravenously injected daily or as indicated until a weight plateau is attained. Subsequently the interval between injections is prolonged to determine the maximum period permitted to intervene between maintenance injections.

PACKAGING: MERCUHYDRIN (meralluride sodium solution) is available in 1 cc. and 2 cc. ampuls.

effect on the chronic eruptions caused by arsenic The keratoses and multiple epithelioma caused by arsenic render BAL, which is a safe drug, worthy of trial in most of the chronic arsenical dermatoses in order to reduce the body content of the offending element

Radiodermatitis

Shafer and her associates have recently reviewed the records of 160 patients with late roentgen injuries observed during fifteen years up to 1947 [9] They found that 39 cases (24 3 per cent) occurred after roentgen ray therapy for nondermatologic conditions, chiefly carcinoma of internal origin. Another 20 patients (12 5 per cent) exhibited radiodermatitis from fluoroscopy or occupational radiodermatitis (physicians, dentists, physicists, x-ray technicians, and veterinarians), and finally, 16 patients (10 0 per cent) showed radiodermatitis that followed treatment for hypertrichosis Their figures indicate that chronic radiodermatitis from the treatment of dermatologic conditions is rare, having an incidence of approximately 1 in 14,000 cases, according to records from the Presbyterian Hospital during the past fifteen years, and 1 in 600 from private dermatologic practice where many patients with this condition are referred for consultation and treatment

Careful analysis of Shafer's charts shows that of the 85 patients with chronic radiodermatitis who were treated for dermatologic disorders, 59 (69 4 per cent) were treated for conditions in which there is no excuse for chronic radiodermatitis, chiefly because newer methods of treatment have rendered x-ray treatment obsolete (Table 1)

TABLE 1.—CONDITIONS TREATED WITH X-RAY FROM WHICH 59 PATIENTS DEVELOPED RADIODERMATITIS

Diagnosis	Number of Cases
Acne or rosacea	25
Sycosis vulgaris	8
Hand eruptions	7
Allergic eczema	5
Dermatophytosis	3
Psoriasis	3
Lupus vulgaris	2
Pruritus vulvae	2
Lupus erythematosus	1
Furuncle	1
Onychomycosis	1
Leukoplakia	1
	59

The remaining 26 cases reviewed by Shafer were treated for hemangiomata (nine), plantar warts (five), keloids (four), "undiagnosed dermatoses" and "chronic dermatitis" (five), tinea capitis (two), and nevus (one)

While Shafer and her associates presented their material with particular reference to exit dose as being instrumental as a cause of radiodermatitis these statistics deserve further comment in view of recent developments in treatment

Where formerly x-ray therapy was considered an essential part of the treatment of acne vulgaris, since the work of Rosenthal and Kurzrok, Lawrence and Werthessen, Hamilton, Barber, and others, it now appears that the administration of female sex hormone to male and female patients with acne, in addition to the other measures usually employed, and the administration of sulfadiazine or sulfapyridine and penicillin in pustular cases will render the use of x-ray seldom necessary [10–13] At an earlier date, with the introduction of chemotherapeutic and antibiotic drugs for local and systemic use, the use of x-ray for sycosis vulgaris and furuncles became outmoded

Extensive clinical trial of undecylenic acid in the treatment of psoriasis as suggested by Perlman is being carried out [14] Preliminary results are encouraging Although cancer rarely supervenes in patches of psoriasis, this disease has long been subject to hazardous treatment by means of x-ray, arsenic, and long-continued application of tar and ultraviolet light exposures Any safe means of therapy will reduce the hazards of treatment

The administration of calciferol in lupus vulgaris is clearing up many severe cases of this disease which is one of the recognized precancerous dermatoses

In lupus erythematosus, another precancerous dermatosis, the cautious use of gold sodium thiosulfate and bismuth subsalicylate injections is constantly showing its worth More recently, the introduction of large doses of synthetic alpha-tocopherol is proving useful This latter medication is usually prescribed by us as Ephynal Acetate in 300- to 400-mg doses daily * This drug has given fewer side-reactions than the naturally prepared, mixed tocopherols Treatment along these lines, rather than with x-ray, radium, and caustic potash, should lower the incidence of epithelioma in lupus erythematosus However, Ryan has pointed out that over a hundred cases of epithelioma in lupus erythematosus have been reported in which none of the above-mentioned physical agents had been used in treatment [15]

In allergic eczema, the administration of antihistamine drugs orally and locally bring a great measure of relief while causative factors are being tracked down, at the same time reducing the need for radiotherapy in eczema The introduction of ammoniacal silver nitrate for the treatment of onychomycosis shows considerable promise and may obviate the need for x-ray treatment in these cases [16]

* Hoffmann La Roche Inc Nutley New Jersey

reason, and (5) prompt examination of any suspicious skin lesions Surely, no attempt is being made to belittle or underestimate the value of sunlight in moderate and reasonable amounts, and, indeed, there are many individuals to whom no harm will come from actinic exposure because of influences of heredity, skin color, sex, and constitutional disposition

The responsibility of dermatologists and other medical men employing ultraviolet light and roentgen rays in treatment is still greater Recently, Coblentz cited the work of Rusch, Kline, and Baumann in which white mice were exposed to prolonged and excessive doses of ultraviolet irradiation [5] The amounts of radiation used could not be tolerated by human skin Yet, after exposures for one hundred thirty-five days, 50 per cent of the mice developed skin tumors By doubling the number of days of exposure, the incidence was increased to 70 per cent These results were obtained only in the so-called "mid-ultraviolet range" (wavelengths of 2,967, 3,024, and 3,132 angstroms), and when cold quartz mercury arc radiation was used, with the greatest amount of energy produced at 2,537 angstroms, no tumors were produced These experiments cannot, however, be made to apply directly to human subjects Blum points out another discrepancy in that epitheliomas in human beings caused by actinic rays are almost entirely limited to the epidermis, whereas most of the tumors produced in mice are in the dermis [6] Coblentz goes on to state that, for home use, the employment of the cold quartz type of ultraviolet light is impractical because these shorter rays are most potent in producing photophthalmia Then he issues a warning that in spite of the lack of any reports showing that "home lamps" have been the cause of cutaneous neoplasms their indiscriminate use, along with excessive sunbathing, offers a potential hazard. The same facts must be borne in mind by the physician who is using ultraviolet light therapeutically

Seborrheic and Senile Keratoses

A word should be devoted to the management of seborrheic and senile keratoses Both types occur, once again, among those persons who have had prolonged actinic exposure, but these keratoses are also seen in patients in which actinic exposure does not seem to be an important factor This is particularly true of seborrheic keratoses which occur in almost as great numbers on the body as well as on the backs of the hands, and face and neck, which are the most frequent sites for senile keratoses

Seborrheic keratoses are raised, light or dark-brown or black lesions with a greasy surface While the number of such lesions is high, the incidence of malignant transformation, which is usually basal cell in character, is extremely low Statistics on this point are difficult to obtain. Suspicion should be directed, however, particularly to those seborrheic keratoses which show infection or are subject to chronic irritation. Recently, Sachs *et al* have distinguished between a seborrheic keratosis and a seborrheic verruca [7] They show evidence that the former evolves into the latter and, while doing so, undergoes clinical and histologic changes, viz, the lesion becomes larger, darker in color, more indurated, and may exhibit dilated, plugged follicular orifices Histologically, the lesion becomes thicker and more acanthotic with a coarse epithelial network in which islands of connective tissue and horn cysts are seen The inflammatory reaction in the cutis is greater They further express the belief, and logically so, that malignant transformation is more common in the seborrheic verruca than in the seborrheic keratosis They state that the basal cell epithelioma and the mixed cell epithelioma are the commonest conditions developing from such seborrheic verruca, with prickle cell and anaplastic epithelioma being less common.

The senile keratoses, more frequently seen on the exposed parts of the body, are discrete, flat, or slightly elevated, verrucous or keratotic, usually scaly, grayish-brown or black growths A little erythematous halo may surround the lesion Malignant transformation, usually into squamous-cell epithelioma, is not uncommon and may be as high as 25 per cent, according to Montgomery and Dorffel [8] Basal-cell epithelioma arises less often from this type of lesion Sachs *et al* recognize clinical and histologic differences between the flat and "papillose" or greatly hyperkeratotic senile keratosis and use the old term senile verruca with its meaning restricted to those keratoses that develop from papillose senile keratoses showing greater potentialities of becoming malignant [7] They state that, histologically, in a senile verruca, when the acanthosis is so great that the rete pegs are obliterated so that the epidermis presents a smooth margin, the proper designation is senile acanthoma They believe that, in both the senile verruca and acanthoma, anaplastic and prickle-cell epithelomata not infrequently arise In our opinion, these observations are correct and concisely presented

Arsenical Keratoses

Although it is generally conceded that BAL (British anti-lewisite) is most effective in acute dermatoses caused by the arsenicals, in several cases that have come to our attention BAL seems to have shown a slight but nevertheless salutory

ROUTINE MANAGEMENT OF CARCINOMA OF THE SKIN AND LIPS

HERBERT L TRAENKLE, M D , Buffalo, New York

(*From the Roswell Park Memorial Institute*)

AS POINTED out in the discussion of problem cases presented before this section two years ago, the treatment of cancer of the skin and adjacent mucous membranes must be individualized to cope with the peculiar features of each malignant lesion [1] A high percentage of cures cannot be obtained by the application of a routine, rule-of-thumb treatment scheme utilizing the same modality in the same way in any and all lesions regardless of type, size, location, or other complicating features On the other hand, in some situations any one of several different methods may be expected to give equally good results

Bearing such limitations in mind, it is possible, however, with the use of established general principles and accumulated statistical experience to formulate more or less broad outlines of treatment methods that can be successfully applied to specific types of lesions in a fair majority of instances The variety and flexibility of such treatment schemes are determined by the physical facilities at hand and by the personal ability of the therapist Obviously, there will be considerable variation in the routines employed and consequently in the scope of therapy available in different offices and institutions

The following is a general outline of the treatment methods we are employing at the present time

Radiation

The majority of previously untreated malignant lesions of the skin and lips are treated with roentgen rays Moderate low voltage with a peak of 100 kilovolts (half value layer 1 5 mm aluminum) is used for most lesions of moderate thickness A target skin distance of 18 cm. is employed In very small lesions (requiring a field size of 1 5 cm diameter or less) a single dose of 3,500 r is sometimes used * However, in most instances and in all lesions requiring a field size of over 1 5 cm. diameter, a protracted divided dose scheme is employed This usually consists of a total of 4,000 to 5,000 r administered over an eight- to twelve-day period. The total surface dose is selected on the basis of that required to give an adequate dose at the furthest depth of the lesion The fractionating of the dose is determined by the surface area of the field size required. The larger the area to be treated, the smaller and more numerous the fraction doses Areas with a diameter of 3 5 cm or less are usually treated in four to five sessions of equally divided doses Fields larger than 10 square centimeters are treated with daily fractions

Lip lesions in which some depth of penetration must always be assumed, even though not readily apparent or palpable, are routinely given a surface dose total of 5,000 r The fractionation is determined by the field size

This dosage scheme in the intermediate voltage range is essentially the same as that now being used by others The time-dose relationship is comparable to that employed by Strandquist in Europe and Hale and Holmes in this country [2 3]

Higher voltages with a peak of 140 to 200 kilovolts (half value layer 0 4 mm. copper to 0 9 mm copper) are used for very thick and bulky lesions The total surface dose given to these ranges from 4,500 to 6,000 r The increments are usually administered daily for ten to twenty days or more as determined by the size of the area

Very low voltage (45 kilovolts, half value layer 0 3 mm. aluminum), short distance (2 0 cm.) radiation with the Phillips tube is used in some situations We have found this feebly

Presented at the 143rd Annual Meeting of the Medical Society of the State of New York, Buffalo Section on Dermatology and Syphilology May 5 1949

* All figures for doses include backscatter

In the treatment of some hemangiomata, plantar warts, keloids, and tinea capitis, x-ray and radium still have a definite place Even in tinea capitis, however, local treatment with new fungicidal preparations is yielding a high percentage of cures, and plantar warts are more and more being treated by desiccation, acids, and other effective measures Radiodermatitis following the treatment of plantar warts, keloids, and hemangiomata is fortunately rare and does not occur with dosage and technic now in standard use by recognized dermatologists who have been thoroughly trained not to treat those lesions that have been previously irradiated by others without ascertaining the doses previously administered

Shafer has not included cases of radiodermatitis following the treatment of epithelioma by x-rays or radium [9] Cutaneous reactions are generally less violent than they used to be This is one of the advantages of fractionization and the divided-dose technic now used We have never seen roentgen epithelioma arising in the atrophic scars caused by such reactions, although theoretically such manifestations are within the realm of possibility Our clinical experience has been so extensive that, if they ever occur, they must be so scarce as to be of no practical importance

During the next decade we may expect that, on the whole, the need for x-ray treatment will be much less than it has been in the past, and radiodermatitis will become scarcer and scarcer Our diplomates of the American Board of Dermatology will not cause radiodermatitis However, we must remember from the statistics of Shafer *et al* that almost half of the cases of chronic radiodermatitis are caused by nondermatologists

Recently, the senior author of this paper reviewed the experimental work of Cowdry, Rhoads, and Martin and Koop, all of which seemed to bear out the fact that, " cells in which cancer develop are sick cells They are sick from nutritional deficiencies and disturbed metabolic activities for a considerable time before malignant transformation develops "[17–20] For example, Cowdry studied epidermal carcinogenesis in mice by applying methylcholanthrene to the skin He noted that before cancer develops the epidermis becomes hyperplastic and "a new precancerous epidermal equilibrium" is attained By chemical and biochemical analysis, a decrease in total lipid, calcium, iron, and biotin have been shown There is a late increase in cytochrome oxidase activity, and there is slightly more magnesium, pyridoxine, and water Cowdry states, "It is safe to say that the conditions of cell life of the cellular population as a whole have been fundamentally changed The cells must face deprivations and hardships to which epidermal cells are not normally subjected As is to be anticipated in making the necessary adjustments, the cells change They swell and become larger in cytoplasmic and nuclear volume, but the nucleocytoplasmic ratio declines We think, and I may be a little visionary, that there is a possibility that multiple deficiencies are factors in making the conditions of cell life so arduous that mutations result "[17] Rhoads had previously demonstrated protection against the carcinogenic effect on the liver of ingested butter yellow in experimental animals by dietary constituents of which one is riboflavin [18] Martin and Koop also reported on the relationship of precancerous lesions of the mouth to avitaminosis B and the response of these lesions to yeast, liver extracts, and similar substances [19]

In 1946, Amersbach, Walter, and Sperti reviewed the previous work on tumor respiration and reported on their own series of basal cell epitheliomata treated with local injections of spleen and liver extracts [21] Of 21 patients treated, 14 were apparently cured, one failed to respond, and six were still under treatment at the time of writing It seemed logical, therefore, to treat severe chronic radiodermatitis in which the development of cancer had occurred or seemed imminent with intramuscular injections of crude liver extract in the hope that it would prevent the development of epitheliomas Gratifying results have been obtained during the last three years in several cases Patients who were for several years developing four to eight epitheliomas every three or four months have had no epitheliomas in a couple of years These have been reported by the senior author recently It is hoped that others may try this form of treatment "Because of the severity of the disease and the great problem it offers to the dermatologist and to the surgeon, it is hoped that some constructive medicinal therapy may decrease the need for more radical surgical measures "[20]

Our own experience with this method is too limited for evaluation as it has been restricted to a few selected cases Because of the time and personnel required by this procedure it does not easily lend itself to employment as a routine where the case volume is heavy

Follow-up Routine

Although histologic cell type is not a determining factor in the choice of treatment for basal and squamous cell cancers, the metastasizing potential of the latter justifies a closer and longer follow-up schedule

Following treatment, patients with basal-cell epitheliomas are seen for a checkup in three months, again in three months, and then every six months until a three-year observation period has been completed Lesions larger than average and those which have constituted a therapeutic problem where the probability of recurrence is expected to be greater than usual necessarily require more frequent inspection

Following the completion of treatment of a squamous-cell (or intermediate type) epithelioma of the skin or lips, the patient is seen in four weeks, then every two months for the first year During the second year, visits are spaced at three-month intervals, and after the second year the treated site and its lymph gland area are inspected every six months until a five-year observation period has been completed

The treatment of metastases from cutaneous and lip cancer is not included in this discussion because it is felt that such presents an entirely separate problem which does not come within the scope of dermatologic therapy Likewise, the management of malignant melanoma has been omitted from this presentation

EARLY RECOGNITION OF POSSIBLY DANGEROUS NEVI (MOLES) AND THE BEST PROCEDURE TO AVOID DEVELOPMENT OF MALIGNANT MELANOMAS (NEVOCARCINOMA)

Eugene F Traub, M D , New York City

(From the Department of Dermatology, New York Medical College and Flower and Fifth Avenue Hospitals)

IN THE original draft of this paper, quoting the statement of Pollitzer, made over thirty years ago, that "a pigmented nevus should be left in peace or else radically, surgically excised," I felt that, in essential knowledge, we had gained but little, even in the past fifty years [1] We may be sure that Pollitzer was not the first to emphasize this vital point which, if invariably followed as a "rule," would keep us out of most of our difficulties, and every recent cancer warning would not have to emphasize this statement again and again However, after reading the recent editorial in the *Journal of the American Medical Association*, entitled "Cancerous Melanoma" and the article reprinted in *New York Medicine* entitled "Melanoma," originally published in the *Texas Cancer Bulletin*, I believe the dermatologists, at least, have advanced their knowledge to a remarkable degree that becomes apparent only when contrasted to the abysmal ignorance displayed by the authors of these articles on cancer propaganda As they are both printed in medical journals, one would presume that they were written for the benefit of the physician primarily and hence one would presume that some degree of accuracy should be expected Instead, lay terminology is used—I refer particularly to the term "mole" which should only be employed by laymen or possibly in articles for lay consumption as it has no scientific or medical meaning whatever, anymore than saying the growth started as a "lump" or, to mention another inaccuracy, "papilloma" which is used by all surgeons as a common preoperative diagnosis for any elevation of the skin I particularly wish to challenge the statement of the *Texas Cancer Bulletin* that "there is no way to predict which benign moles are destined to develop into melanomas " This point has been settled many years ago, and it is well known that all malignant melanomas or nevocarcinomas develop from the pigmented lesion that has been described as a junction nevus because of its

Presented at the 143rd Annual Meeting of the Medical Society of the State of New York Buffalo Section on Dermatology and Syphilology May 5 1949

penetrating radiation especially useful in very small superficial epitheliomas in locations where it is desirable that the underlying structures receive a minimum of radiation Most frequently such areas are the external ear, tip of the nose, the scalp, and the dorsum of the hand In this newer field of soft radiation, dosage schemes have been less well explored than with the more conventional qualities We have successfully treated a considerable number of lesions with a single dose of 5,000 to 6,000 r This dose is quite similar to that employed by Howes and Camiel [4] It is to be remembered, of course, that this dose is given to a very small area, since the maximum field obtainable with the tube at 2 cm distance is 2 5 cm diameter Studies are now under way to investigate the further potential scope of the usefulness of this type of radiation The recent introduction of beryllium window tubes for use in ordinary x-ray apparatus will allow for a much wider usage of softer radiation

The absolute necessity for precision in outlining the field to be irradiated, in selecting the appropriate quality and quantity of irradiation to be delivered, and in the actual setup and administration of each treatment is to be emphasized These are the functions of the physician therapist and are not to be delegated to technicians, nurses, etc Outlining the field for radiation is no less important than deciding on dosage One of the most frequent causes of recurrences is failure to consider the fullest potential peripheral extent of the tumor and to realize that microscopic invasion may be present under normal skin at a considerable distance beyond the visible limits of the lesion Although tables for arbitrary margins in relation to field size have been worked out and to a limited extent are useful, the proper appraisal of the field requires long experience in all types of lesions and locations Tissue dose and depth dose charts for the type of apparatus used are prerequisite in selecting the appropriate quality and in computing the optimum dose to be delivered to each lesion This is especially important in treating the larger areas where steering between overdosage and underdosage is frequently extremely difficult

Electrosurgery

Electrosurgery in the form of electrocoagulation has a limited but definite range of usefulness This method of therapy can be efficaciously employed in very small epitheliomas and especially so in lesions recurring in a previously irradiated area where further radiation would be inadvisable Also we have employed this modality extensively in the multiple small epithelomatous nodules occurring in cases of late radiodermatitis of the face where complete excision and repair of the entire atrophic area is usually not feasible Electrocoagulation is the simplest and probably the best method of removing senile keratosis in the prophylaxis of cutaneous cancer Likewise it can be applied to leukoplakia of the lip and accessible portions of the oral mucous membrane In spite of contrary reports in the older literature our experience with this modality in large and penetrating skin cancer has not been encouraging

Electrocautery with a flat tipped applicator is very useful in treating broad, flat, superficial, so-called eczematoid or psoriasiform superficial basal cell epitheliomas which would otherwise require excision with large graft for repair The resultant scar is sometimes cosmetically objectionable, however, and, therefore, such a therapeutic approach is limited to lesions on the trunk.

Lesions involving the rim of the ear lend themselves very nicely to excision with the electric knife The epithelomatous area and free margin including cartilage can easily be amputated under local anesthesia No suturing is necessary The remaining portion of the pinna heals in a few weeks The result is usually excellent This procedure has been illustrated and described in a previous communication [1]

Scalpel Surgery

Surgical excision and repair is routinely performed in all but the very smallest recurrent epitheliomas where irradiation, in one form or another, had been previously used (Electrocoagulation is employed in the very small ones) Likewise, this approach is regarded as the one of choice in most epitheliomas of more than 3 cm in diameter which are situated on the forehead, scalp, dorsum of the hand, or below the knee Lesions with a diameter of 1 5 cm or more, occupying the concha of the ear or in which the external canal has been invaded, are treated surgically

Surgical excision is the method of choice in most large bulky lesions of the lip or commissures Where an epithelioma of the lip is surrounded by leukoplakia, the entire area including the tumor is excised

Although no modality yields a very high percentage of cure in far-advanced cutaneous cancer which has penetrated underlying bone, probably most of these are more profitably approached with scalpel surgery

Chemosurgery

Mohs has demonstrated in an impressive number and variety of cases that so-called "chemosurgery" can achieve results in carcinoma of the skin and lip which compare favorably with those obtained with radiation or scalpel surgery [5 6]

nevus are as follows Usually a relatively smooth, slightly elevated pigmented lesion, the color variable but usually dark brown or blackish (slate-colored or bluish-black is more often the color of the blue nevus), it is usually devoid of hair as an essential part of the lesion (exceptions), it is generally small in size measuring from a fraction of 1 cm to 3 to 4 cm. in size (large lesions are frequently mixed types), it is usually not verrucous or pedunculated, but exceptionally it may be either The junction nevus has been confused with the nevocarcinoma, angiosarcoma, blue nevus, intradermal nevus, benign pigmented epithelioma of Bloch, pigmented basal cell epithelioma, hematoma, angioma, hydrocystoma, pyogenic granuloma, dermatofibroma, puncture tattoo (pencil or ink), and sarcoid, to name those personally encountered Of these, the greatest difficulty exists in differentiating the various nevi, one from the other Clinically, this is sometimes extremely difficult as a blue nevus, an intradermal nevus, or a benign pigmented epithelioma may frequently closely resemble a junction nevus

Therefore, it becomes expedient to do a microscopic examination on the tissue This brings up the question of a biopsy Because one of the dangers lies in the fact that nevi are apt to be mixed in type (blue nevus and junction in same lesion, etc), a section from one area might not be characteristic of other parts of the same mark, and since most junction nevi are relatively small in size, I believe it is advisable to excise the mark in toto in order to obtain a complete histologic opinion on the entire growth As a punch biopsy usually requires novocaine and a suture, excision really presents little in the way of additional surgery No wide margins need be taken at this time, but the excision should go well below the skin and subcutaneous tissue If the report should be unexpectedly adverse, then additional measures may be undertaken at once This saves the average patient from unnecessarily large excision, in the first instance Cosmetically, excision offers about as good a method of treatment as can be selected for most nevi The results from freezing, desiccation, electrolysis, or chemicals are usually not satisfactory, even from the cosmetic standpoint, in the case of junction nevi Therefore, excision is the procedure of choice in dealing with junction nevi that require any type of intervention From the standpoint of safety to the patient, it is immaterial whether a scalpel or "electric knife" is used for the excision, but if preference must be stated, it should be in favor of the "electric knife"

The verrucous nevi, having varying degrees of pigmentation and which lie in the epidermis (intraepithelial), may also terminate in cancer Warty nevi are usually easily identified clinically The warty character, generally without much pigment (exceptions) and with hairs as a variable feature, together with the usually bizarre shape or linear configuration, resemble few other growths Since the lesions are intraepithelial, they are usually quite superficial They may be removed by desiccation, curettement, freezing, and, in selected instances, by radiation (not the benign pigmented epithelioma of Bloch) While they may terminate as carcinomas, not nevocarcinomas, on the whole they represent relatively benign lesions The benign pigmented epithelioma of Bloch may not be warty at all but consists only of pigment found entirely in the epidermis It has been described as a relatively smooth lesion but may present slight thickening or elevation, so that it may be confused with a flat junction nevus which it otherwise does not resemble, since it always remains benign No treatment is indicated for this nevus unless it is removed for diagnostic or cosmetic reasons

The intradermal nevus is undoubtedly the most common of all the nevi in this group with the junction nevus probably ranking next in frequency followed in turn by the intraepidermal nevus The blue nevus is encountered less often but is by no means so rare as was once supposed The pure intradermal nevus is a benign lesion and always remains benign Only when the intradermal nevus is mixed with one of the other types of nevi does the possibility of malignant change arise Because the nevus cells lie at a depth in the cutis in nests and strands well below the epidermal-dermal junction, one might suppose that this nevus would give the clinical impression of lying at a depth as does the blue nevus On the contrary, however, as one looks at these flesh-colored or slightly pigmented nevi, their abrupt elevation is striking, and they appear as if they were more superficially than deeply located Strangely enough, superficial desiccation to skin level completely arrests them, although hairs, if present, may have to receive special treatment The remarkable thing also is that, following such removal, which seems utterly inadequate when looking at the histopathology, the nevi show no tendency to regrow Occasionally, reports that intradermal nevi terminated as basal cell epitheliomas have appeared in the literature These errors have occurred because the patient gave the history that a "mole" preceded the appearance of the lesion, proved to be an epithelioma, whereas it actually began as an epithelioma The same mistakes occur with trichoepitheliomas Even years of shaving over these lesions, naturally

origin at the epidermal dermal junction This is the only lesion that gives rise to such a change All other nevi either always remain benign or give rise to changes other than malignant melanomas

What then, if so much vital information has long been known, can we add now? Just this Not everyone can take the time necessary to attempt to unravel the almost hopeless confusion befogging this subject, largely by virtue of the vague and indefinite terminology which leads one author to employ a term to describe a certain lesion that another will apply to an entirely different malformation Nevi, because they may appear in bizarre patterns, encourage physicians to give rein to their imaginations and create new names that are entirely without meaning, as a rule, except possibly that they might be slightly descriptive of the clinical picture As a result, one reads all too frequently, as in the *Texas Cancer Bulletin*, that a "mole running wild is brutal" It is generally impossible to learn with any degree of accuracy what the original growth actually may have been, but, frequently enough, it probably was not a "mole" or nevus of any type If the original growth actually was a nevus, it would be of the utmost interest to know its exact type as a matter of future knowledge To say that it started as a "mole" or papilloma is equivalent to saying nothing at all

It is a well known fact that nevi do not develop cancer in excess of normal cells When one considers the tremendous numbers of nevi that are found on all individuals and the rarity with which they are complicated by cancer, this is certainly true However, the subject of nevocarcinoma is emphasized by these facts (1) because nevi are so common, it is the more startling when a "mark" that has long been considered benign suddenly gives rise to trouble, (2) when it does occur, nevocarcinoma may be and quite frequently is one of our most rapidly fatal tumors, and (3) that in most, if not in all cases early recognition of a dangerous type lesion followed at once by its prompt and adequate removal could have forestalled a fatal outcome Therefore, in my opinion the crux of the whole subject is to distinguish the various nevi one from the other so that we can recognize the dangerous ones early and remove them at once

Our most dangerous nevi are the pigmented and warty varieties Those which originate in and are confined to the epidermis may remain benign or may terminate as cancer, nevus cells are not present Nevi arising at the junction between epidermis and cutis, the so-called "junction nevi," may give rise to nevocarcinoma (malignant melanoma), or they, too, may remain benign throughout life This may be our most dangerous lesion and should be the one to recognize Two varieties that are considered benign lesions are the intradermal nevus and the blue nevus, both found relatively deep in the cutis. The blue nevus may rarely terminate as a melanosarcoma, but few acceptable cases of this kind are on record Unfortunately, nevi may be, and not infrequently are, mixed in type, and this fact probably accounts for many of the unhappy accidents that have occurred For example, a mark that presents the clinical features usually attributed to a benign lesion is treated by desiccation, freezing, chemicals, or some other method short of radical extirpation, and promptly a nevocarcinoma results What has occurred indicates that in some clinically unrecognizable portion of the lesion a junction nevus was present and was activated by inadequate treatment Everyone can relate innumerable instances in his own experience In fact, in my opinion, that it does not occur with much greater frequency is the best proof of the generally benign character of most nevi Nevi are treated with almost equal abandon by most chiropodists, electrolysis experts, not to mention the family physician, surgeons, and dermatologists

Strangely enough, surgeons are some of the worst offenders Instead of regularly excising nevi as one might expect them to do, they all too frequently apply acids or desiccate, and, to a surgeon, any elevation of the skin, regardless of its character, is a "papilloma" The only thing that keeps them out of greater difficulties is the fact that the pathologist gives them the correct diagnosis when they do excise the lesion, and they may then correct original blunders

The problem, then, would seem to be a simple one Learn to distinguish benign nevi that have no malignant potentialities from those that might become malignant Unfortunately, some of the potentially benign nevi may clinically resemble the possibly malignant ones so closely that this cannot always be done Of course, we can all recognize sudden rapid growth, change in color, bleeding, ulceration, etc , in a pigmented nevus, but those symptoms, which were once given us as "early signs," we now know are, in the main, relatively late manifestations We now like to recognize the junction nevus while it is benign, and if it is located at a point of continuous or oft-repeated pressure or trauma as on the feet or hands, belt or girdle line, recommend that it be prophylactically removed *It is not* feasible to remove all junction nevi, as many individuals have literally hundreds of them scattered over all skin areas Practically all of them remain benign throughout *life, it is only* the exceptional one that goes bad if left alone

The features that characterize the junction

FIG 1. Small area of radiodermatitis simulating a plantar wart

FIG 2 Typical area of plantar radiodermatitis with small ulcerations, varying sized blood vessels, and scar tissue

titis frequently simulates warts, and many times the patient's history of previous treatment does not reveal the use of x-rays or radium (Fig 1) Larger areas on the plantar surface resemble similar areas on other parts of the body with erythema, telangiectasis, and atrophy The larger areas are relatively easy to diagnose, but small areas, 1 cm and less, are at times very difficult to differentiate from warts and corns The smaller the patch, the more difficult it is to diagnose

Most cases of plantar radiodermatitis are the result of treatment for corns, calluses, and warts Because of these original lesions, plantar radiodermatitis usually occurs over bony prominences Even after the original lesion has disappeared, pain still persists because of the pressure of the underlying bony points on the fibrotic radiodermatitis

A thorough history of previous treatment in all cases of plantar lesions, whether it be corn, callus, wart, or radiodermatitis, is necessary It is important to note whether or not irradiation has been given, what type—roentgen, radium, or Grenz ray, the number of treatments, and the dates and the amount of irradiation. Frequently, the patient will give a history of irradiation from more than one physician. If one decides to treat a lesion with further irradiation, it is imperative to learn from the preceding operators the type and amount of irradiation given, the date of treatment, and the size of the portal It is much safer not to give further irradiation therapy if it has already been used, no matter what type of lesion is present The only exception is a malignancy

Most small areas of plantar radiodermatitis when first seen are painful and are covered with a hyperkeratotic mass This must be pared down until the area is approximately as thin as the normal surrounding skin. Only now can a true diagnosis be made The corelike mass does not have the well-marginated border of the usual plantar wart or corn but, instead, has a diffuse border which blends into the surrounding tissue Scarring is evident, and, thus, the normal papillary lines of the sole are interrupted At times, small horny nuclei or islands are present in the scarred area Pain on walking is frequently present An important feature is the presence of desiccated capillary tips varying in size (Fig 2) These may or may not be perpendicular to the surface In a mosaic wart the capillary tips are all the same size and perpendicular to the surface [2]

In severe cases of plantar radiodermatitis, there may be localized areas which simulate plantar warts in size and appearance When these are pared down, the center appears soggy and is made up of many small sinuses which give a honeycomb appearance The next stage is ulceration with more intense pain The appearance of ulceration is strong evidence of radiodermatitis.

The ulcers vary in size in proportion to the radiation absorbed They may be minute, 1 mm in diameter, or they may be larger, up to 1 cm or more The small ulcers are usually round but may appear linear because of the approximation of the opposing surfaces of the ulcer A constant feature of these ulcers is pain, even while the foot is elevated The larger the ulcer the greater is the pain Secondary infection is more apt to be present in the surrounding tissue with erythema and dusky, boggy edema The base of the ulcer is often necrotic Surrounding these ulcerations are typical areas of radiodermatitis

Even in minor cases of plantar radiodermatitis, there is some destruction of the underlying fat pad The greater the involvement, the more extensive the loss Where there has been extensive destruction with deep fibrosis, the involved area is not freely movable over the underlying structures With extensive ulceration, necrosis of the underlying bone may occur

Often adjacent to the patch of plantar radiodermatitis are mosaic warts These are the

resulting in repeated cuts, seems to do them no harm Most intradermal nevi do not appear until the age of puberty or later, and, while they may occur anywhere, they are most commonly found on the face Single lesions may occur, but much more frequently they are multiple After reaching the size of from several millimeters to about one centimeter (except in the case of extremely large lesions that may be present from birth), they usually remain stationary The color varies from that of normal skin to dark brown Hairs are more generally present than not

I am sure that for years the blue nevus, the blue-black or slate-black mole, was mistaken for a junction nevus or even for an early nevocarcinoma It is a benign growth generally, although, rarely, it may terminate as a melanosarcoma Montgomery and Kahler in a review of the reported cases felt that only one or two could be accepted as bona fide examples of such a change [2] The elongated, spindle-shaped nevus cells of the blue nevus are of connective tissue origin and usually are found relatively deep in the cutis or about the adnexa The amount of pigment present and its depth determines the color of the lesion. Not all are blue or blue-black, rarely they may be dark brown or even relatively light brown in color The blue nevus is harmless and is only removed when situated in areas of extreme trauma or for diagnostic purposes to rule out nevocarcinoma or junction nevus

It may be seen that the clinical recognition of the various types of nevi is not always easy Now add to this the fact that several types may be found in the same growth. Such mixtures can only be identified from examination of serial sections, as clinically nevi usually only suggest the predominant type growth that is present It is these mixed lesions that frequently appear to be responsible for exceptions to the rule. Since these mixed types occur with relative frequency, they provide the strongest and most unassailable argument for excision biopsy of all nevi in this group in which there is the least doubt as to their character Excision is the treatment of choice for all nevi that are suspect or that are in areas where irritation and trauma are factors One must remember also that it is impossible to excise all junction nevi and that most of the junction nevi are not strictly precancerous lesions and normally follow a benign course No harm can result from leaving benign nevi alone, but inadequate or ill-advised tampering with dangerous nevi without the benefit of a guiding microscopic examination is malpractice of the worst kind at the present time. If, in addition, we can teach surgeons and the self-styled "cancer experts" to drop the lay terms of "mole" and "papilloma" and substitute modern scientific terminology, even though this will require a little clinical preoperative diagnostic knowledge on their part, it may represent our biggest advance in this field in the past half century

THE PROBLEM OF PLANTAR RADIODERMATITIS

Andrew H Montgomery, M D , Royal M Montgomery, M D , and Donald C Montgomery, M D ,* New York City

RADIODERMATITIS is usually a difficult problem to handle, not only because of the disability entailed but also because it is considered by many as a precancerous dermatosis Except in the case of postoperative irradiation at the site of malignancies, there is no excuse for plantar radiodermatitis Common corns, neurovascular corns, and mosaic warts are known to be radioresistant [1] Radiotherapy is definitely ineffective on calluses so they should never be treated by this method Yet, all dermatologists have had patients with some type of radiodermatitis caused by someone's carelessness or the persistent use of roentgen, radium, or Grenz rays Usually, these cases are the result of inadequate shielding, intensive dosage, prolonged treatment, and poor judgment in the choice of therapy

Radiodermatitis anywhere on the body is difficult to treat, but it is particularly difficult on the plantar surface of the foot because of the weight-bearing function of the foot It is also difficult to diagnose because plantar radioderma-

* By invitation

Presented at the 143rd Annual Meeting of the Medical Society of the State of New York Buffalo Section on Dermatology and Syphilology May 5 1949

FIG 4. Large patch of mosaic warts with satellites on left foot Plastic repair for radiodermatitis on right foot following roentgen therapy for mosaic warts.

to prevent recurrence The devitalized tissue is not just limited to the small ulcer or corelike mass but includes a margin of the apparently healthy skin The disadvantage of this method is the scar left by the normal healing process with its subsequent pain. There is no fat pad cushioning the area This all tends to give a poor weight-bearing surface

Skin grafting is used with more satisfactory results [4] A wide excision of the devitalized area is made down to healthy tissue If there is a sufficient fat pad remaining, a Thiersch graft or free full thickness graft may be used According to Ghormley and Lipscomb, these grafts often fail to correct the defects over a weight-bearing surface, especially over bony prominences (Fig 4) [5] In these cases and in those with extensive involvement, an untubed pedicle graft from the opposite calf or prepatellar area may be used The pedicle graft gives a thicker fat pad and, consequently, a more satisfactory weight-bearing surface.

Ghormley mentions a ninety-day postoperative disability with this method However, Shaw states that his patients walk in normal shoes in from six to eight weeks [6]

Even though a skin graft has been made, a protective pad is often necessary to relieve pressure properly over these areas

Dickson recommends a more radical procedure which has given excellent results [7] This consists of the excision of a V-shaped area from the foot including a toe, metatarsal bone, and the area of radiodermatitis The only disadvantage is that the foot is narrower than the normal one The main advantages are that the intractable ulcer and persistent pain are gone and the patient has a good weight-bearing foot

Any plastic repair of the foot is out of the domain of the dermatologist and should be done by a surgeon who is well acquainted with this type of reconstruction

Few areas of plantar radiodermatitis become malignant The authors have never seen a small area of plantar radiodermatitis develop into a cancer Some cases have been observed for years The authors do not believe that all areas of plantar radiodermatitis must be removed, because they feel that they are not all precancerous When an area continues to grow despite therapy, it should then be considered a potential cancer Perhaps the absence of actinic light in a shoe is a factor in keeping these areas free of cancer Certainly, one sees more cancer developing in areas of radiodermatitis on the hands and face than on the foot In line with Andrews' research, liver therapy may help in the prevention of malignancies following plantar radiodermatitis

The problem of plantar radiodermatitis is not a simple one Proper diagnosis must be made first, and the small areas must not be confused with warts Following the diagnosis, one must make a choice between the longer conservative method and the shorter surgical one

Summary

The diagnostic features of plantar radiodermatitis have been described

Treatment has been outlined and divided into conservative and surgical therapy

Conservative therapy is recommended for small areas of plantar radiodermatitis without ulceration, and in cases where the ulcers are small it should be given a trial

Reconstructive surgery is advised immediately for cases with ulceration in an area of 0 4 cm. or more

remnants of the original lesion for which irradiation had been given without success

Treatment

Treatment of plantar radiodermatitis may follow either of two methods, conservative or surgical The conservative type is directed toward healing the area and preventing ulcer formation by means of soothing or stimulating remedies and protective padding This method is recommended mainly for small areas with or without ulceration The majority of small radiodermatitis patches on the sole will respond to this treatment It is wise to try the conservative method for two to six months before resorting to surgery

Since pain is the chief subjective symptom, relief of the pain is the first concern in conservative treatment Locally, the area should be pared down to remove the hyperkeratotic tissue This alone will frequently relieve much of the pain incurred by walking The area is thinned down until active blood vessels are seen or pain is elicited A sharp scalpel should be used to minimize bleeding and pain Medications such as ointments containing cod liver oil, urea and/or tannic acid may be applied Aloe vera jelly may also be used, but it is difficult to keep in place if the patient is ambulatory Where there is ulceration, bed rest is necessary together with penicillin therapy Two to five million units may be necessary over a period of one to three weeks Andrews has used liver and penicillin therapy in a few of these cases to aid healing and also to prevent carcinoma [3] His results have been very encouraging

If the patient is ambulatory, pain is diminished by applying protective pads to relieve pressure on the area involved These pads may be made from felt or foam rubber, cut into a crescent or horseshoe shape to fit behind and around the involved area The pad is strapped in place with adhesive A more permanent appliance is a removable insole, with the proper pad incorporated in it A cast of the foot must be taken before a correctly fitted insole can be made This type will obviate the constant renewal of pads applied to the foot and the irritation of the skin by adhesive tape Pads may also be glued into the shoe but they must be properly placed and correctly shaped Proprietary pads are not satisfactory since each pad must be shaped to the individual needs of the patient

In some cases a complete insole of foam rubber is necessary to relieve the pain of walking A small pad applied directly over the area, cushioning it, is helpful These are mechanical substitutes for the partially lost fat pad

In extensive patches of plantar radiodermatitis without ulceration, the patient may be comfortable for years by paring down any calloused area every month or two and wearing a protective cushioned insole

FIG 3 Radiation ulcer with adjacent active mosaic warts treated by two series of x-rays

With this type of conservative treatment some small areas involved become smaller, desiccated blood vessels become less numerous, and the area less painful Ulcers also have been healed If after two to six months there is no sufficient progress and decrease in pain, surgery may be performed

With ulceration, in order to regain normal function of the foot without pain, surgery will often be needed (Fig 3) In fact, where the ulceration is 0 4 cm or larger, it is probably better for the patient to be treated immediately with reconstructive surgery, for the disability will be less in the long run. To give better weight bearing surfaces over bony prominences, surgery is necessary

Various methods of reconstructive surgery have been recommended Some are more desirable than others, but no matter what surgical procedure is followed, infection first has to be removed by bed rest and penicillin therapy

The simplest surgical method is excision of the involved area This must be thoroughly excised

serologic and presumed reinfection Seroresistance is included as failure in treatment In other words, if the titer had not reached negativity sometime during, and then remained so throughout the entire eighteen months, these were considered failures

We had five seronegative primary patients of whom all were cured Of 16 seropositive primary cases, 15 were cured—a cure rate of 94 per cent Thirty-eight cases of secondary syphilis were part of our series Of these, 31, or 81 per cent, were cured Early latent (less than one year in duration) infections numbered 25 There were 18 cured, 72 per cent (Table 1)

TABLE 1.—RESULTS IN FIVE-DAY THERAPY

	Cures	Failures	Total	Per Cent Cured
Seronegative Primary	5	0	5	100
Seropositive Primary	15	1	16	94
Secondary	31	7	38	81
Early asymptomatic (less than one year duration)	18	7	25	72
Totals	69	15	84	82

Results

Unquestionably, our series is small However, we were able to follow a high proportion of our patients for the entire observation period of eighteen months, so the satisfactory results are believed to be of definite significance When the 20 cases which we were unable to follow for the entire observation period are compared with the 84 cases reported, we find that except for a lower percentage of primary cases the proportion is about the same (Table 2)

TABLE 2.—PROPORTION OF PATIENTS FOLLOWED

	Primary	Secondary	Early Asymptomatic
Cases reported	21 (25%)	38 (45%)	25 (30%)
Cases not followed	2 (10%)	11 (55%)	7 (35%)

Using as a basis our classification of failure in treatment outlined above, the accompanying table shows that our results compare favorably with those of Chargin and Thomas where longer treatment schedules were employed (Table 3) [3,5]

TABLE 3.—RESULTS OF TREATMENT OF EARLY SYPHILIS WITH PENICILLIN IN OIL AND BEESWAX

	Thomas *et al.*		Chargin *et al*		Our Series	
	Number	Cured	Number	Cured	Number	Cured
Seronegative Primary	59	93%	13	100%	5	100%
Seropositive Primary	159	86%	51	92%	16	94%
Secondary	372	62%	83	75%	38	81%
Early asymptomatic (less one year in duration)			6	67%	25	72%

Spinal fluid investigations were done on 27 patients sometime during the observation period Two of these were classified as treatment failures One of the latter had a positive spinal fluid All other specimens were negative

It might be worth while to point out that all patients were questioned at each return visit regarding any penicillin therapy for intercurrent infections during their observation period As far as we were able to determine, there were no such occurrences

Summary

Final results of therapy of 84 patients with early syphilis (less than one year in duration) are reported These findings are compared with others, previously published, in which larger doses and longer treatment periods were used It appears that results with this scheme of treatment with an ambulatory penicillin preparation does not vary significantly from the others It is again emphasized that an advantage of this method is the fewer number of patient visits needed to complete the treatment The time when one treatment for early syphilis will be sufficient may not be far off It is hoped that this contribution will be a small step on the way

333 LINWOOD AVENUE

Discussion

Rudolph Ruedemann, M D, *Albany*.—The percentage of cures in darkfield positive, Wassermann negative primary, and Wassermann positive cases in early syphilis after a thorough trial period is an established fact. The maintenance of a definite serum level of penicillin over a time period of at least seventy-two hours, whether with aqueous penicillin, procaine penicillin, or the newer preparations, gives uniform results

We are now particularly concerned with that 25 to 30 per cent of patients, maintaining a positive Wassermann, relapsing or the reinfections, which are difficult to ferret out from the relapses, although the percentage of relapse is estimated from 10 to 40 per cent by various authors

Systems of treatment, variable as to intensity and time, some with arsenic-bismuth combinations, are being put forth A recent report from Chicago in which thirty-hour treatment fever therapy was given using penicillin, mapharsen, and bismuth gives 13 per cent failure [a] Is this too tricky and expensive for routine use? Keim recently advocated 15 daily injections, 300,000 units in Wassermann negative, darkfield positive, primary syphilis with added eight weeks of 16 arsenical and 8 bismuth injections for seropositive primary [b] In secondary syphilis this is followed by ten more injections of 300,000 units of penicillin

Reports come in from all sections of the country, different schedules but all with the one purpose—a higher cure rate, but are we getting into the same old rut—increasing the time and the number of

FIVE-DAY AMBULATORY PENICILLIN THERAPY OF EARLY SYPHILIS

NORBERT G RAUSCH, M D , Buffalo, New York

(From the Buffalo General Hospital)

THERE appears to be little controversy over the fact that the number of patients completing antiluetic treatment varies inversely with the length of time required for completing such therapy Records show that only one out of every five patients who started an eighteen-month clinic treatment scheme completed it Only one out of four such patients received the minimum of 20 arsenical and 20 bismuth injections In sharp contrast are the results of a ten-day ambulatory penicillin in oil and beeswax regime in Almeda, California [1] Approximately 98 per cent of 952 patients who started on such a plan of treatment completed it Eighty per cent missed no clinic appointments Obviously, the shorter the plan of treatment, the more cooperation from the patient

The literature contains many articles on penicillin therapy in a delaying absorption vehicle for early syphilis Thomas *et al* gave 600,000 units of penicillin in oil and beeswax per day for eight days [2] Total dosage was 4,800,000 units Ninety-three per cent of 59 patients with seronegative primary syphilis remained seronegative, 86 per cent of 159 patients with seropositive primary syphilis were cured Only 62 per cent of secondary luetics were cured Chargin *et al* gave 300,000 units daily for sixteen days, a total dosage of 4,800,000 units [3] They treated 13 patients with seronegative primary syphilis All were cured Of 51 cases of seropositive primary syphilis, 92 per cent were cured About 75 per cent of 83 cases of secondary lues were cured Only six cases of early latent syphilis (less than one year in duration) were *part of their series* Two of these six cases remained positive during the observation period, the cure rate being 66 per cent

Blackwood and his group in New York believe that results in the series of cases they report suggest that increasingly large doses of commercial penicillin may not be superior to smaller doses administered over similar short periods of time [4] Prolonging the treatment period from eight to fifteen days improved treatment results according to Thomas [5] Experimentally, Eagle and his coworkers reported on cures of syphilitic rabbits by such small doses that penicillin was never *demonstrable* in the blood [6] They found that low concentrations of the drug acting over a long period of time were more effective than high concentrations acting over a short period. In summary, it would appear from the references cited above that our scheme of treatment, i e , relatively large doses in a short period of time (five days) might not be as efficient as longer treatment periods (eight to fifteen days) with perhaps no increase in total dose

The efficacy of penicillin G treatment in early syphilis is unquestioned The problem, as it now appears, is to find the shortest period and optimum dose over which the antibiotic can be given which will result in a large percentage of cures With this in mind, we instituted in November, 1946, a study of 104 patients with early acquired syphilis on a five-day treatment regime These individuals received individual daily doses of 600,000 units of crystalline sodium penicillin G in peanut oil with 4.8 per cent bleached beeswax The manufacturer maintains that such a preparation given at the rate of 600,000 units daily gives a serum penicillin level of 1 0 units per cc four hours after injection and 0 14 unit per cc twenty-four hours after injection Such a dose amounted to a volume of 2 cc., and the total amount was given in one depot intramuscularly in the buttock The great proportion received five such daily injections consecutively A few cases received the five doses in a six-day period, thereby skipping one treatment day The total amount of penicillin given in each case was 3,000,000 units

Material

These individuals were seen in the diagnostic clinic of the venereal disease division of the then City of Buffalo Health Department * Penicillin was supplied by the New York State Department of Health All treatments were given in the diagnostic clinic by the writer All completed the prescribed course of therapy We were able to follow 84 cases for the entire eighteen months The post-treatment observation consisted of titered serologies and physical examinations at monthly intervals The results given below include only those individuals who were followed the entire eighteen months The classification of treatment failure includes relapses, clinical and/or

Discussion

Rudolph Ruedemann, M D , *Albany*.—The percentage of cures in darkfield positive, Wassermann negative primary, and Wassermann positive cases in early syphilis after a thorough trial period is an established fact The maintenance of a definite serum level of penicillin over a time period of at least seventy-two hours, whether with aqueous penicillin, procaine penicillin, or the newer preparations, gives uniform results

We are now particularly concerned with that 25 to 30 per cent of patients, maintaining a positive Wassermann, relapsing or the reinfections, which are difficult to ferret out from the relapses, although the percentage of relapse is estimated from 10 to 40 per cent by various authors

Systems of treatment, variable as to intensity and time, some with arsenic-bismuth combinations, are being put forth A recent report from Chicago in which thirty-hour treatment fever therapy was given using penicillin, mapharsen, and bismuth gives 13 per cent failure [a] Is this too tricky and expensive for routine use? Keim recently advocated 15 daily injections, 300,000 units in Wassermann negative, darkfield positive, primary syphilis with added eight weeks of 16 arsenical and 8 bismuth injections for seropositive primary [b] In secondary syphilis this is followed by ten more injections of 300,000 units of penicillin

Reports come in from all sections of the country, different schedules but all with the one purpose—a higher cure rate, but are we getting into the same old rut—increasing the time and the number of

injections but losing sight of the fact that with these the patient grows weary?

It has been interesting to observe the development of antiluetic treatment over a thirty-year period The twenty-year, gradual evolving from the sterlisans magna dose to a one and one-half year routine with the arsenicals-mercury and then bismuth This was seemingly well established, the treatment par excellence, only to be upset by the five-day intensive therapy with its hospitalization and reactions, an expensive but effective procedure It had its five-year trial and then on the horizon, in 1943, appeared penicillin, an entirely new approach, an antibiotic, first requiring around-the-clock hospitalization therapy but soon becoming a five-day ambulatory routine, relatively free from reactions, short, inexpensive courses with results comparing favorably with outmoded drugs These features met with one hundred per cent cooperation on the part of the patient This cannot be overlooked as a most valuable asset In our clinics, we have yet to see a patient who has failed to carry out this treatment (The follow-up is another story) This is indeed a far cry from the 35 per cent or even less than 25 per cent who completed one and one-half years routine

New public health problems have arisen added zeal is required to control sources of infection and contacts to prevent reinfections, added effort in follow-up work to check relapses This was particularly necessary because overzealous newshawks led the patients to believe that five days sufficed—this was a cure for all forms of syphilis

This paper reiterates the established fact that the earlier the treatment, the better the results, but in early syphilis, Wassermann positive, the ultimate goal has not been reached Perhaps the newer preparations, with their longer maintenance of penicillin, blood serum levels, will be the answer to the syphilologist's prayer

In striving for the goal, we must not lose sight of the mental and economic status of the average patient with syphilis The individual at the end of the needle does not always have the cerebration to envision the dire consequences of treatment neglect as has the wielder of the syringe The time of treatment must conform with the patient's economic status—no loss of time from his work, plus his inclination to appear for treatment with not too many explanations necessary to his employer In Vermont a most recent report bore out these facts, when out of 193 patients, all white, 49 (25 4 per cent) took irregular treatments mostly because of failure to set a proper time [c]

After listening to Dr Rausch's paper, coupled with personal experience, we cannot help but feel penicillin is the drug of choice in early syphilis, but new developments must be along these same lines—short, inexpensive therapy, readily available

Why strive for that added 25 to 30 per cent of cures by increasing time and the number and the variety of injections, when perhaps 30 per cent or more of the patients become weary and disinterested and drift back into promiscuity with their relapses!

The Parran goal will never be reached until, educationally and therapeutically, our efforts are concentrated on the patient with early syphilis and we finally achieve Utopia, when the 33 per cent early syphilis and 67 per cent late syphilis, now reported in our State, is reversed to 67 per cent early syphilis and 33 per cent late syphilis Only then will our goal be in sight

TEN POINTS

1 You cannot bring about prosperity by discouraging thrift

2 You cannot strengthen the weak by weakening the strong

3 You cannot help small men by tearing down big men

4. You cannot help the poor by destroying the rich.

5 You cannot lift the wage-earner by pulling down the wage-payer

6 You cannot keep out of trouble by spending more than your income.

7 You cannot further the brotherhood of man by inciting class hatred

8 You cannot establish sound security on borrowed money

9 You cannot build character and courage by taking away a man's initiative

10 You cannot really help men by having the government tax them to do for them what they can and should do for themselves.

—*Committee for Constitutional Government, New York City*

CUTANEOUS LEISHMANIASIS—REPORT OF A CASE AND SUMMARY OF THE NEWER CONCEPTS

MARVIN N WINER, M D , Buffalo, New York

(From the Department of Dermatology, Edward J Meyer Memorial Hospital)

CUTANEOUS leishmaniasis is not a new disease, having first been described by Russell in 1756 [1] It was not until 1903 that the causative organism was first accurately described by Wright The description of the causative factor by Wright showed it to be a protozoan organism of the family *Trypanosomidae* This flagellate has the property of infecting vertebrates but utilizing invertebrates as intermediate hosts Leishman later changed the name of the etiologic organism to Leishmania tropica [2]

Several excellent articles have been published in the last fifteen years by Fox, Dostrovsky, and numerous South American authors [3 4] A splendid review was published by Goldman in 1947 [5] The epidemiologic importance of cutaneous leishmaniasis has been overstressed, since all of the reported cases (as well as my own) were exogenous in origin The case reported as autochthonous by Benedek was dismissed by Fox as having originated in Poland [6] The report of Stewart and Pilcher of an autochthonous case in an American-born Mexican boy was questioned by Goldman because the diagnosis was based solely on the findings of the Leishmania organisms in tissue section.[7] Furthermore, it has been shown that cutaneous leishmaniasis is primarily a self-limited disease Experience with American troops stationed in the middle East showed that, of 499 proved cases occurring in these soldiers, there were few actual cases when these troops were returned to the continental limits of the United States [8]

There are several classifications of leishmaniasis given in the literature A simple and logical grouping, based on anatomic involvement, is as follows

(*a*) Primary cutaneous (oriental sore) caused by L tropica

(*b*) Primary cutaneous with secondary visceral involvement (Espundia or Uta, South American leishmaniasis) caused by L braziliensis

(*c*) Primary visceral—Kala-azar caused by L. donovani, and infantile splenomegaly caused by L. infantum.

(*d*) Primary visceral with secondary cutaneous involvement (post-Kala-azar leishmanid)

There has been considerable controversy regarding the ability to distinguish morphologically between L. tropica, braziliensis, and donovani That all three are variants of a single organism has been repeatedly suggested This question is important and not only from an academic point of view Are the three strains immunologically related? Noguchi, quoted by Sutton, claims that Leishmania tropica, braziliensis, and donovani are serologically specific, yet fermentation tests are not adequate to distinguish between them.[2] Is prophylactic immunization in endemic areas indicated? In Bagdad, Persia, and Turkestan, prophylactic inoculation of children has been practiced for many years. Graduated dosages of culture material of L tropica have been used, the children developing cutaneous ulcers at the site of inoculation which last for two or three months [9] Upon involution of these ulcers, immunity develops, presumably permanent.

The methods of transmission have not been fully established to date Reservoir hosts include the Macacus monkeys, cats, and brown bears Dogs and white mice have been successfully inoculated [10] The sandfly, genus Phlebotomus, is almost universally accepted as a vector for the Leishmanial parasite Different species of the Phlebotomus are involved in different parts of the world Stable flies, house flies, ticks, and bedbugs have all been incriminated as possible vectors, but the mere presence of the flagellates within the bodies of these bugs does not necessarily mean that they are true vectors The bodies of L. donovani have been isolated in the nasal discharges of humans, as well as in the urine and feces [11]

Whether the respiratory method of transmission is of importance has not been established Autoinoculation does occur, and contact from person to person is a distinct possibility In France, however, the disease does not have a tendency to spread in wide areas Climatic conditions must have some bearing on transmission

It is questionable whether the Phlebotomus fly must actually bite the host (the proboscis penetrating the skin) The excreta may contaminate the skin abrasion when the insect alights on the skin [12] Slapping an insect and crushing it against the skin is sufficient for inoculation to take place However, despite the crushing of

Presented at the 143rd Annual Meeting of the Medical Society of the State of New York, Buffalo Section on Dermatology and Syphilology May 6 1949

the insect with the hands (palms) in the case of oriental sore, to my knowledge the palms as a site of oriental sore have never been reported The difference in thickness and toughness of the skin on the palms, as contrasted with the face for example, probably is the important point However, I feel that minute breaks in the skin are much more likely to occur on the hands than on other parts of the body

Southwell and Kirshner have dissected many sandflies and have found that the leptomonad or flagellate form is present only in the pharynx of the flies, while the Leishmania, or nonflagellated forms, are present in the midgut of the insects [12] When the leptomonad form is inoculated into the human, no infection results, while inoculation with the Leishmania type almost invariably produces infection This would indicate that an actual bite by the insect is not likely to result in infection unless material from the gut is forcibly injected during the biting process Whether an insect possesses the powers of regurgitation, I do not know

The diagnosis of cutaneous leishmaniasis is not always easily made In nonendemic areas, such as the United States, a high index of suspicion is not maintained In Latin America, however, one hears the dictum that ulcers above the waist are leishmaniasis, while those below are the so-called tropical ulcers [5] The lesion usually begins with a discrete papule on the exposed portion of the body This enlarges to become a nodule which may either be level with the surrounding skin (deep nodule) or elevated in the classic manner The nodule then undergoes ulcerative changes, and the entire lesion finally heals with atrophic scarring The scar usually assumes a spindle-shaped pattern Various laboratory measures have been used in the diagnosis of cutaneous leishmaniasis These include direct examination of smears taken from the ulcer, culturing, vaccine test, examination of blood smears, formol-gel test, and biopsy or tissue examination

Of the methods enumerated, direct microscopic examination of the stained smear is perhaps the best Unfortunately, the incidence of positive results in proved cases is not one hundred per cent Dostrovsky and Sagher state that smears are negative in 10 per cent of cases of cutaneous leishmaniasis, despite excellent conditions in experienced hands [13] Culturing on the N N N medium (Nicolle-Novy-NcNeal) and, more recently, the egg embryo medium yields a satisfactory incidence of positive results

Sagher recently cited two cases of recurrent leishmaniasis with no parasites present on smear or culture but giving a positive vaccine test in a dilution of 1 10,000,000 [14] This author claims that the vaccine test is one of the more important laboratory procedures in making the diagnosis of leishmaniasis He reported 84 cases of cutaneous leishmaniasis of the early nodular type, all showing a response to a dilution of 1 100 and 1 10,000 Sagher claims that the recurrent types and the early types with lymphogenic spread show a reaction to the vaccine test in a much higher dilution, ranging from 1 10,000 to 1 10,000,000 This indicates an extremely allergic reaction similar to the papulonecrotic tuberculid and implies that a positive vaccine test is indicative of an immunologic reaction to an endoprotein or possibly a toxin elaborated by the Leishmania organism

The examination of the peripheral blood smear is of little value, except that monocytosis has been reported in several instances The formol-gel test is by no means pathognomonic In leishmaniasis, a cloudy gel is elaborated, as contrasted to the clear type gel found in other diseases

The pathology of leishmaniasis is not pathognomonic, being very similar to blastomycosis, except that many plasma cells are scattered diffusely throughout the tissues in leishmaniasis, and no microabscesses are found within the epidermis (Satenstein) [1] Weidman claims that the pathology is tuberculoid but not distinctive [1] Wenyon, quoted by Goldman, claims that the identification of the Leishmania parasites in sections is always open to question unless made by an observer who has had extensive experiences with these particular organisms [5]

Treatment

The treatment of cutaneous leishmaniasis may be divided into three main categories I will not go into detail, other than to mention the principal agents used

Local Treatment with Chemicals—Among the chemicals which have been used are tincture of iodine, pure phenol, local injections of berberine sulfate, red cell paste, etc

Physical Modalities—Dry ice and x-ray have been used It is interesting to note that MacKee in his most recent textbook does not even mention leishmaniasis as a condition amenable to x-ray [14] Auerbach mentions a prompt cure within two months after a total dosage of 750 roentgen units (factors not given) [16]

Systemic Treatment—Tartar emetic was first introduced by Vianna for the treatment of South American leishmaniasis in 1913 [17] In 1916, Caronia used the pentavalent antimony compounds Stibacetin and Stibinyl.[17] Since that time it has been found that the pentavalent antimony compounds are far superior to the trivalent

Army Institute of Pathology

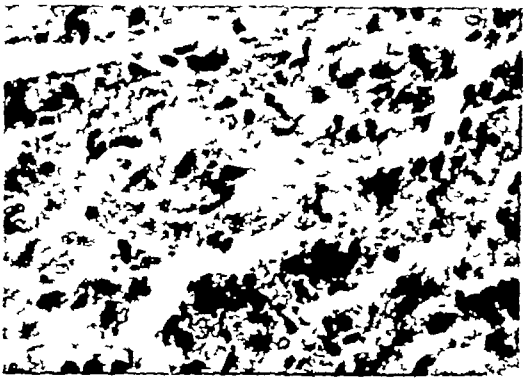
FIG 1 Photograph of patient showing appearance of lesions at first examination Ulcer, lower left margin, was biopsy site

Army Institute of Pathology

FIG 2 Low-powered magnification showing relatively normal epidermis and tuberculoid infiltration in the midportion of the corium.

compounds [15] Of the former, no drugs are superior to Stibanose, Neostam, or Neostibosan The therapeutic effects of the drugs seem to be correlated with the concentration of antimony in the spleen (experimental leishmaniasis of hamsters) The exact mode of action of antimony is conjectural Whether the antimony molecule actually destroys the parasites or merely stimulates a mechanism of resistance to the infection is debatable Suffice it to say that the pentavalent antimony drugs are superior agents in the treatment of cutaneous leishmaniasis Vaccine treatment, using killed organisms from a culture of L tropica in the dose of one half million parasites, has been used with debatable results

The report of the thirty-second exogenous case of cutaneous leishmaniasis from the United States follows



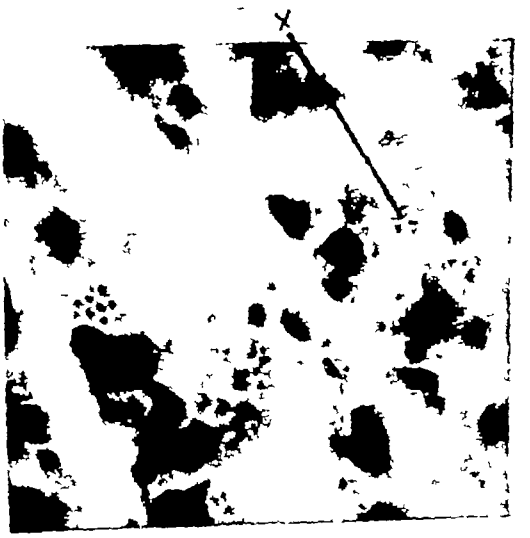
Case Report

M H, a white, twenty-four-year-old man, was referred by a physician for diagnosis and treatment on October 31, 1947 He gave the history of coming to the United States from Palestine on or about July 2, 1947, four months prior to his first examination Ten weeks after entering the United States, he noted a painful inflammatory lesion on the upper margin of the bridge of the nose He emphatically denied a previous insect bite. Local hot moist dressings were used in conjunction with a sulfathiazole powder, followed by the intramuscular use of penicillin in oil and beeswax With the response being unsatisfactory after five days of this treatment, the patient was referred by his family physician (Fig 1) The referring physician had noted some peripheral extension of the lesion with pinhead globular papules appearing at the margins.

Except for attacks of seasonal pollenosis and bronchial asthma, the past history and functional inquiry were noncontributory

The general medical examination was negative Temperature, pulse, and respiration were normal The dermatologic examination revealed an erythematous plaque extending across the bridge of the nose measuring 1 1/4 inch in the horizontal diameter and 3/4 inch in the widest portion of the vertical diameter The upper margin of the plaque began 1/4 of an inch below the glabella. With the crust removed, the base was composed of healthy granulation tissue with a few globules of mucopurulent debris scattered irregularly over the surface

The tentative diagnoses were leishmaniasis and blastomycosis A culture was taken from the



Army Institute of Pathology

FIG 3 Intermediate magnification showing macrophages and plasma cells with an occasional epithelioid cell. The Leishman bodies are seen within the macrophages

margin of the lesion (after curettage by means of a fine curet and capillary pipet) The culture was implanted on blood agar (the only available medium at the time) A punch biopsy was taken from the left lower margin of the plaque.

Subsequent laboratory examinations revealed the following The blood Wassermann test was negative, the red and white blood count and hemoglobin tests were all within normal limits, the urinalysis was normal, and repeated cultures (six) implanted on blood, Sabaraud, and N N N media merely revealed a few gram-positive organisms resembling staphylococci Repeated smears (including smears made by compressing the removed biopsy tissue on slide) using Giemsa's stain were all negative.

Pathologic examination of the tissue sections revealed the following The epidermis was ulcerated at one margin. Except for the presence of a few lymphocytes and an occasional mononuclear leukocyte in the lower granular layer, the epidermis was normal. In the midcorium several tuberculoid aggregates were seen (Fig 2) These were primarily composed of epithelioid cells, lymphocytes, and plasma cells (Fig 3) Large pale-staining cells with a single pink nucleus were seen Within the margins of these large cells, many discrete, round and oval, light-staining bodies were seen (Fig 4) These parasites were occasionally found outside of the margin of these cells, apparently because of rupture of the limiting cell membrane

Army Institute of Pathology

FIG 4. High-powered magnification showing large, pale-staining cells (macrophages) containing the Leishman bodies. An occasional blepharoplast is seen (X)

Summary

1 A report is made of the thirty-second exogenous case of cutaneous leishmaniasis in the United States and Canada

2 The methods of transmission of this disease are reviewed The bite of the sandfly is, in itself, not necessary as a means of transmission.

3 Newer laboratory methods of diagnosis including the cultural and intradermal vaccine methods are briefly outlined

315 LINWOOD AVENUE

Discussion

Harold L Walker, M D , Elmira —This case report and comprehensive review of the literature on cutaneous leishmaniasis is timely This is particularly true in these days of increasing air travel to endemic areas, such as the Mediterranean, Near East, Orient, and South America. Due to the relatively long incubation periods of the various types of cutaneous leishmaniasis, an individual could become infected in an endemic area and return to the United States prior to the onset of clinical symptoms Therefore, such reports as this should serve to remind us that tropical diseases, such as cutaneous leishmaniasis, are not medical curiosities but diseases any of us may be called upon to treat in our private practices. Even though such tropical cutaneous diseases are relatively uncommon, patients with nodular or noduloulcerative lesions occurring on exposed areas such as the face should be questioned as to whether or not they have traveled in endemic areas If a history of such travel is obtained, the various types of cutaneous leishmaniasis, such as oriental sore, post-kala-azar dermal leishmaniasis, and American leishmaniasis, as well as the more common nodular lesions, must be included in the differential diagnosis.

In the fall of 1944, I had the opportunity to observe cases of both oriental sore and post-kala-azar dermal leishmaniasis in the clinics at the Tropical School of Medicine in Calcutta, India. Dr Winer has described the clinical features of oriental sore which is due to L. tropica and which occurs chiefly in hot dry climates like the western part of India.

Of course there are many variations in addition to the typical papular or nodular type Among these are the verrucous and the lupoid type. Clinically, the verrucous type closely resembles verrucous tuberculosis In the lupoid type, which is occasionally referred to as leishmaniasis recidiva, the original papule heals with scarring, and new papules occur at the border and spread peripherally The lupoid type, as the name implies, resembles lupus vulgaris

The condition, post-kala-azar dermal leishmaniasis, is a very interesting entity Kala-azar, so-called visceral leishmaniasis due to L. donovani, occurring in hot moist areas with altitude below 2,000 feet, such as eastern and southeastern India, presents certain clinical features such as irregularly remittent fever, emaciation, anemia, and enlarged liver and spleen When the visceral infection is overcome either by treatment or spontaneously, some of the organisms occasionally remain in the skin and slowly multiply When this occurs, about one or two years later post-kala-azar dermal leishmaniasis may develop One of the early symptoms is an erythematous eruption involving the middle third of the face, resembling rosacea. In addition, hyperpigmented macules, pinpoint to about $1/2$ inch in diameter, may develop with the distribution similar to that of pityriasis rosea involving the neck, trunk, extremities, and also occasionally the face As time goes on, the hyperpigmented lesions, as well as the erythematous areas, may become nodular Apparently post-kala-azar dermal leishmaniasis is rare in other areas, but more than 1,000 cases of this condition have been recorded at the Tropical School of Medicine in Calcutta, India

RING DEATHS "SHOCKING," CHICAGO EDITOR CLAIMS

The shocking incidence of ring deaths and serious injuries among professional boxers make the "sport" the greatest killer in American athletics, says Thomas Gorman, Chicago, assistant managing editor of *Hygeia*, health magazine of the A.M.A.

Boxing has produced more deaths per number of participants than any other sport, and 50 per cent of active fighters are punch drunk to some degree, he points out in the June issue of the magazine.

"The 13 ring deaths of 1948 form a continuation of a series over the years since professional boxing has become widely legalized in the United States," Mr Gorman says. "According to recent figures, five boxers were killed as a result of bouts up to April 20 this year, 13 in 1948, nine during 1947, and 11 in 1946

"A boxer dosn't have to be knocked out or have his skull broken to be seriously injured He may suffer pinpoint hemorrhages or other harm to his brain not outwardly apparent even to the trained physician

"These injuries can result from any hard blow to the head Pinpoint hemorrhages caused by the concussion from a hard blow may destroy nerve tissues. Brain tissues do not heal as do other tissues of the body

"Some parts of the brain can suffer destruction of a small amount of tissue without immediate paralysis or changes in behavior These injuries are permanent As more are received they will contribute to loss of mental powers or bodily control.

"Doctors who have pointed out the dangers of organized mayhem based on scientific observations over the years are only permitted on the sidelines as members of advisory boards and as medical examiners dependent for their fees on the whims of politicians Use of doctors has the effect of furnishing a phony respectability to an otherwise dubious activity

"The participants for our 'sport' of professional boxing come from the thousands of high school boys and young men in college who engage in amateur boxing This has become so highly organized through vast intercity tournaments that the only division between professional and amateur boxing is the funnel by which the first is supplied with manpower from the great reservoir of the second They are both part of the same picture"

A STUDY OF MATERNAL DEATHS IN NEW YORK CITY FOR 1947

EDWIN M GOLD, M D , and HELEN M WALLACE, M D , New York City

(From the Bureau of Maternal and Child Hygiene, New York City Department of Health)

THE medical profession is particularly interested in securing the best possible care for the expectant mother, in preventing complications involving the pregnant state whether they occur before, during, or after delivery, and in preventing deaths from these complications

One of the most striking methods of illustrating these preventable factors is to study the lessons offered from maternal deaths This then is the reason for the following analysis, in which a study of the maternal mortality for the year 1947 in New York City is undertaken During this period of time there were 171,174 live births and 230 maternal deaths, with a maternal mortality rate of 1 34 per 1,000 live births

The material in this report is taken from data available on death certificates in New York City and supplementary information secured from autopsy reports on 41 per cent of the cases of this series in the office of the Medical Examiner in the City of New York. It should be mentioned at the outset that there is some limitation in this material source, and unquestionably more complete data are present in case reports from hospitals and physicians' records

Table 1 shows the distribution of maternal deaths by borough in New York City for 1947

TABLE 1 —DISTRIBUTION OF MATERNAL DEATHS BY BOROUGH

Borough	Number of Live Births	Number of Maternal Deaths	Maternal Mortality Rate*
Manhattan	53 282	86	1 63
Brooklyn	67 091	76	1 13
Bronx	23 923	39	1 63
Queens	22 418	25	1 11
Richmond	4 460	4	0 89
Totals	171 174	230	1 34

* Per 1 000 live births.

In this group of 230 maternal deaths there are 37 which are not related to pregnancy or the puerperal state, leaving 193 puerperal deaths with a corrected maternal mortality rate of 1 13 per 1,000 live births Fifteen of these cases, or 40 per cent of the nonpuerperal deaths, occurred in patients who were beyond the first month postpartum

Marital Status

An analysis of the marital status of the maternal death group shows that there were 18 single women, three widows, one divorcee, the remainder were married

There were 35 women who had induced abortions and died, of whom approximately 50 per cent were married We call attention to this fact because such a high incidence of deaths associated with induced abortion occurred in the married group

Racial Distribution

Table 2 shows that, in spite of the fact that 11 per cent of the live births in 1947 occurred in the nonwhite group, 27 per cent of the maternal deaths occurred in this group The maternal mortality rate in the nonwhite group is three times higher than that of the white group This fact points the need of more complete availability of medical and hospital care, better education of the nonwhite group of expectant mothers, and better case-finding to assure early and continuous antepartum care

TABLE 2 —RACIAL DISTRIBUTION OF PATIENTS

Color	Maternal Deaths Number	Maternal Deaths Per Cent	Total 1947 Live Births Number	Total 1947 Live Births Per Cent	Maternal Mortality Rate
White	167	73 3	152 836	89 3	1 09
Nonwhite	63	26 7	18 338	10 7	3 44
Total	230	100 0	171 174	100 0	1 34

Length of Gestation

Fifty-seven per cent of the patients died during the third trimester of pregnancy If we include the patients with abortion and ectopic pregnancy whose gestation periods were unknown with the group dying in the first trimester of pregnancy, a total of 20 per cent died in the first trimester of the pregnancy This high incidence of death (20 per cent) in the first trimester is pointed out specifically as a perhaps not too well-appreciated fact (Table 3)

TABLE 3 —MATERNAL MORTALITY IN RELATION TO LENGTH OF GESTATION

Length of Gestation	Number of Patients	Per Cent
First trimester	11	4 8
Second trimester	17	7 4
Third trimester	131	56 9
Postpartum	20	8 7
Abortion gestation unknown	23	10 0
Ectopic pregnancy gestation unknown	0	3 9
Gestation unknown	19	8 3
Totals	230	100 0

Presented at a meeting of the New York Academy of Medicine Section on Obstetrics and Gynecology April 26 1949

Causes of Maternal Deaths

Hemorrhage—In the last compiled national statistics available, hemorrhage is listed as the third cause of maternal mortality, being outstripped by infection and toxemia, respectively [1] In our review of maternal mortality in New York City for 1947, hemorrhage is found as the leading cause of death 53 cases, or 23 per cent, of the 230 recorded deaths (Table 4) It is of interest to us that in a city such as ours where 99 per cent of the deliveries occur in hospitals, such a reversal in trend should be evidenced It is even more startling in the light of this last fact to observe that of these hemorrhage deaths, 10 per cent occurred within one hour postpartum, 20 per cent within two hours postpartum, and 30 per cent within three hours postpartum All deaths due to hemorrhage occurred within the first twenty-four hours postpartum

The reversal of trend referred to above, in which hemorrhage became the leading cause of death, was noted by Gordon in his reviews of maternal deaths in Brooklyn since 1940 [2] Merely to point out the statistical incidence of hemorrhage is fruitless unless this information is translated into day-to-day obstetric practice With this view in mind, our survey discloses the following (1) Blood replacement is a life-saving necessity Every hospital with a maternity service must have an adequate supply of blood for immediate administration (2) Better diagnosis is necessary in cases of ectopic gestation, since 25 per cent of the hemorrhage deaths were in the first trimester of pregnancy of which the great majority were associated with ruptured ectopic gestation.

Infection.—Infection in this series is the second leading cause of death, while nationally it is the leading cause of death [3] In our series of 48 infection deaths, 50 per cent were due to embolic phenomena, approximately half of which were associated with cesarean section (Table 4) The other 50 per cent were cases of frank infection (generalized peritonitis) in which criminal abortion played a major role

Cardiovascular Disease—Deaths from cardiovascular disease are not listed as a separate entity in national statistics of maternal mortality Yet, in our series, cardiovascular disease appears as the third major cause of death, with 42, or 18 per cent, of the cases (Table 4) The major risk of rheumatic heart disease complicating pregnancy is emphasized, since 60 per cent of the cardiovascular deaths were due to this cause These findings demonstrate the need for greater appreciation of the risk and more active participation by obstetrician and internist in the management of the pregnant woman with cardiac disease

Toxemia.—Toxemia in our series ranks fourth as the cause of death, accounting for 12 per cent of the deaths as compared to a national ranking of second place in 1944, with 25 per cent of the maternal deaths (Table 4)

Anesthesia.—Anesthesia deaths, which have heretofore been overlooked in national statistics, have recently been found to be a significant factor in maternal mortality In our series anesthesia accounted for 4 per cent of the deaths and ranked fifth as a cause of death (Table 4)

There are three major approaches to the problem of reducing deaths due to anesthesia Prophylactically, solid food should be withheld from the parturient in active labor In addition, lavage of gastric contents prior to induction of anesthesia, as recently pointed out by Mendelson, is a major step forward [4] The maintenance of a clear airway is to be stressed [5] Finally, top quality anesthesiology practiced by qualified personnel in the field is a necessity, not a luxury, in obstetric practice

Miscellaneous—There were 47 deaths due to a wide variety of causes, of which 37 were nonpuerperal, as previously mentioned

TABLE 4.—CAUSES OF MATERNAL DEATH IN NEW YORK CITY IN 1947

Cause of Death	Deaths	
	Number	Per Cent
Hemorrhage	53	23 0

Unknown	3	1 3
Totals	230	99 7

Comparison of Types of Deliveries

It is acknowledged obstetrically that certain types of delivery are fraught with added risks to the parturient Table 5 statistically portrays these risks, as follows

1 Midforceps delivery appeared in 2 9 per cent of the total 1947 deliveries, while its incidence rose to 3 5 per cent in the mortality series

2 Version without forceps to the aftercoming head had an incidence of 0 2 per cent in the total 1947 deliveries, but its incidence rose ten times in the mortality series to 2 6 per cent

3 The over-all cesarean section rate in 1947 was 3 6 per cent for all deliveries, but its incidence rose five times in the mortality series to 18 2 per cent

4 The apparent 35 times higher incidence of curettage in the mortality series must be qualified by the understanding of the fact that criminal

abortions constituted a great majority of these deaths in the mortality series

5 Ectopic pregnancy appears with a 26 times greater frequency in the maternal mortality series, despite the fact that 10 of these 12 cases died in the hospitals Since eight of these 12 ectopic pregnancies died unoperated and hemorrhage was listed as the cause of death in 10 of the 12, one can but conclude that late or erroneous diagnosis played a significant role

6 Lastly, it is worthy of mention that, despite the fact that 85 per cent of the total deliveries terminated spontaneously or by low forceps, these modes of delivery were associated with slightly more than 25 per cent of the total maternal deaths in 1947

TABLE 5 —Comparison of Total Deliveries with Total Maternal Deaths in 1947 by Types of Deliveries

Type of Delivery	Total Performed in 1947 Number	Per Cent Incidence	Total Deaths in 1947 Number	Per Cent Incidence
Spontaneous	105 005	56 6	34	14 7
Low forceps	53 485	28 3	25	10 9
Midforceps	5 441	2 9	8	3 5
High forceps	115	0 06	0	0 0
Version, no forceps	405	0 2	6*	2 6
Version with forceps	44	0 02	0	0 0

Undelivered	?	?	40	17 3
Other operative procedures	720	0 4	1**	0 4
Not stated	32	0 02	19	8 2
Mutilating procedures	27	0 01	0	0 0
Totals	185 251	99 87	230	99 2

* A craniotomy was performed prior to version on one case.
** This patient died on the table after institution of fractional spinal anesthesia preparatory to cesarean section

Cesarean Section

It has been stated in a recent maternal mortality study that approximately one third of maternal deaths exclusive of those in early pregnancy have been associated with cesarean section.[6] In this 1947 study, 42 women (18 per cent) were delivered by cesarean section Table 6 analyzes the causes of cesarean deaths

TABLE 6 —Causes of Death in Cesarean Section Cases

Cause of Death	Deaths Number	Per Cent
Infection		33 2
Embolism	11	
Postoperative ileus with peritonitis	2	
Intestinal obstruction	1	
Hemorrhage	10	24 0
Toxemia	7	16 6
Cardiovascular disease		14 4
Rheumatic heart disease	4	
Other	2	
Anesthesia		7 1
Spinal	2	
Other	1	
Miscellaneous	2	4 7
Totals	42	100 0

The risk of death from infection in cesarean section is 60 per cent higher than that for the total series

Toxemia, the third greatest cause of cesarean deaths, had a 50 per cent greater incidence as cause of death in the cesarean group than in the total series

Abortion

Of the 41 women who had abortions and died, 35 or 85 per cent had a curettage Of these 35 instrumentalized cases, seven, or 20 per cent, were associated with traumatic perforation of the uterus with intestinal laceration. The cause of death in all of these cases was acute generalized peritonitis proved at autopsy

There were six cases of spontaneous abortion, or 15 per cent of the total abortion deaths Two of these six women died of postabortal hemorrhage, in the other four women, the abortion occurred spontaneously, secondary to the underlying conditions which caused death—namely, two cases of acute appendicitis with peritonitis, one case of intestinal obstruction, and one case of hypertensive cardiovascular disease

Ectopic Pregnancy

There were 12 ectopic gestations in our total series of 230 maternal deaths (5 per cent) Hemorrhage was the cause of death in 10 of these 12 cases, cyclopropane anesthesia accounted for one death, and intestinal obstruction the other

TABLE 7 —Data on Cases of Spontaneous Rupture of Uterus

Case Number	Type of Delivery	Cause of Death	Duration of Labor	Duration of Survival after Delivery	Number of Previous Pregnancies
1	Spontaneous	Hemorrhage	2 hours 5 min.	13 days	2
2	No information	Hemorrhage	No information	2 hours 20 min.	6
3*	Spontaneous	Hemorrhage	No information	14 hours	3
4	Spontaneous	Hemorrhage	9 hours	7½ hours	3
5	Low forceps	Hemorrhage	27 hours	8 hours	7
6	Spontaneous	Hemorrhage	No information	During laparotomy	No information

* Rupture occurred in fundal scar at site of myomectomy performed one year previously

Laparotomy was performed in only four cases (33 per cent) Eight cases died unoperated, the diagnosis was made in these cases on the basis of autopsy findings Ten of these 12 women died in a hospital, two died at home

Spontaneous Rupture of Uterus

Spontaneous rupture of the uterus, while it appears nowhere in our compilation of statistics, occurred in at least six patients The facts of interest in these cases are summarized in Table 7

The most striking evidence elicited from the above data is the fact that, despite survival time ranging from two hours twenty minutes to thirteen days, only one of the six cases was operated It is of further interest to note that no primipara appears in this group The patients had from two to seven previous pregnancies It is also of interest that previous uterine operation (myomectomy) had been performed in only one patient It is of interest that Case 1, who had had only two previous pregnancies, sustained this dire complication after a precipitate labor with spontaneous delivery

Home Deaths

There were 15 women who delivered and died at home with a maternal mortality rate of 4.7 per 1,000 live births, compared to the over-all rate of 1 34. Thus the home maternal mortality rate is three and one-half times that of the over-all mortality rate for New York City in 1947 It is of interest that five patients who delivered at home died of hemorrhage, and three patients died of infection One of the infection deaths was due to septicemia This finding demonstrates the hazard of home delivery, particularly when one-third of these cases died of hemorrhage How can the emergency of postpartum hemorrhage, to list but one obstetric emergency, be adequately coped with in the home? It is hoped that future years will see a total disappearance of home deliveries in this city

Economic Status of Patients

It is becoming more and more an accepted fact that mortality in obstetrics is a product of preconceptional, ante-, intra-, and postpartal factors In other words, it reflects the entire status of the patient Prophylactically, therefore, one must deal with the developmental, nutritional, emotional, and systemic aspects of the patient on the one hand and the environmental (social and economic) factors on the other hand What more graphic portrayal of the above factors can be made than to demonstrate the more than 100 per cent difference in maternal mortality rate between the private patients with a rate of 0 7 and the ward patients with a rate of 1 9 per 1,000 live births (Table 8)

We stated at the outset that only 41 per cent of the cases were autopsied If more knowledge regarding maternal mortality is to be gleaned, certainly a higher percentage of women who die should be studied at the autopsy table

TABLE 8.—ECONOMIC STATUS OF PATIENTS

Economic Status	Patients		Live Births	Maternal Mortality Rate
	Number	Per Cent		
Private patients	95	41 3	124 134	0 7
Ward patients	84	36 5	45 378	1 9
Unknown	51	22 2		
Totals	230	100 0	169 512*	

* There were an additional 1 662 live births distributed as follows ambulance 1 150 midwife 121 nurse-midwife 343 foundling 32 other 16 making a total of 1 662 births

Condition of Child or Fetus

Table 9 shows that 37 per cent of women in this group had a living child In 57 per cent of the women there was pregnancy wastage, i e, the child was stillborn, aborted, and not delivered or ectopic

This pregnancy wastage should be compared with the 1947 city-wide statistics, in which there were 185,251 total deliveries, 171,174 live births and 14,077 fetal deaths The total reported pregnancy wastage, city-wide, was, therefore, 8 0 per cent

From these figures it is obvious that fetal wastage is seven times higher in our group of maternal mortality cases than in the total women who delivered in 1947 in New York City

TABLE 9.—STATUS OF CHILD OR FETUS

Status of Child or Fetus	Number of Patients	Per Cent
Child living	86	37 4
Child stillborn (full term or near term)	39	16 9
Child aborted	41	17 8
Child not delivered	40	17 4
Ectopic gestation	12	5 2
Not stated	12	5 2
Totals	230	99 9

Filing of Certificate of Fetal Death

Table 10 is included merely to show the incompleteness of reporting fetal deaths in New York City The Sanitary Code of the City of New York requires that all products of conception, regardless of length of gestation, be reported on a fetal death certificate to the Department of Health.[7] In this series of 89 fetal deaths, only 52, or 58 per cent, had a fetal death certificate filed with the Department of Health. The group in which there was poor filing of fetal death certificates predominantly included women who aborted or who had ectopic pregnancy

In light of the recently growing interest in the field of developmental pathology, the physician can aid in this investigation and preventive program by supplying at least the detailed information asked for on fetal death certificates [8]

TABLE 10.—STATUS OF FILING OF FETAL DEATH CERTIFICATE WHEN FETAL DEATH OCCURRED

Length of Gestation	Total	Fetal Death Certificate Filed	Fetal Death Certificate Not Filed
Third trimester	41	39	2
Second trimester	4	3	1
First trimester	9	6	3
Unknown*	38	5	33
Totals	92	53	39

* Includes abortions and ectopic pregnancies in early pregnancy

Summary

1 The maternal mortality rate for New York City in 1947 is 1 34 per 1,000 live births

2 Thirty-seven nonpuerperal deaths occurred, correcting the maternal mortality rate to 1 13 per 1,000 live births

3 The maternal mortality rate in the nonwhite group is 3 44 per 1,000 live births, a rate three times higher than that in the white group (1 09)

4 Hemorrhage is the leading cause of death (23 per cent) Cardiovascular disease and anesthesia have emerged as major causes of maternal mortality (third and fifth places, respectively)

5 The hazards of version and cesarean section as modes of delivery are demonstrated

6 The dire consequences of late or erroneous diagnosis of ectopic pregnancy are pointed out

7 Six patients died with spontaneous rupture of the uterus, with operative intervention in only one case, despite survival time ranging from two hours to thirteen days following the diagnosis of rupture

8 The risk of home delivery is shown to be three and one-half times greater than hospital delivery (Maternal mortality rate of 4 7 per 1,000 live births compared to 1 34)

9 The more than 100 per cent greater maternal mortality rate in ward patients versus private patients is shown.

10 The striking fetal wastage in the maternal mortality group versus the city-wide pregnancy wastage is presented

11 The incompleteness of reporting fetal deaths in New York City is shown

QUESTION VALUE OF RICE DIET FOR SEVERE HIGH BLOOD PRESSURE

Restriction of table salt by the rice diet or other diets does not appear to be of much benefit in treating patients with advanced high blood pressure, a study made by doctors from Washington University School of Medicine, St Louis, shows

"Restriction of sodium chloride in the diet, either by the rice diet or other means, is usually ineffective when the condition is advanced," Henry A Schroeder, M.D , Melvin L Goldman, M.D , Palmer H Futcher, M.D , and Marlene Hunter, B S , of the Department of Internal Medicine of the School and Barnes Hospital report in the June 4 issue of the *Journal of the American Medical Association*

Of 16 patients treated for high blood pressure, response to the rice diet or other low salt diet was poor in 13, most of whom were suffering from the disease in its severer stages Three patients with milder forms of the disease were benefited

As a possible explanation of the beneficial effects of the diet in some cases of high blood pressure, the authors say that patients may have a condition of which high blood pressure is only one symptom

Six other patients, all obese and all having symptoms suggestive of an alteration in some of the functions of the adrenal cortex (the outer portion of the adrenal glands, located at the upper end of each kidney) were treated by the doctors for high blood pressure All were benefited by a low salt diet

THE SURGICAL TREATMENT OF CHRONIC INTRACTABLE PAIN

JOSEPH H SIRIS, M D , Flushing, New York

(From the Department of Neurological Surgery, Jewish Hospital of Brooklyn)

THIS report is confined essentially to a consideration of the relief of chronic unbearable pain by the surgical interruption of nerve pathways transmitting or influencing pain impulses for the patient whose pain is not amenable to any other form of treatment

Although such measures are not employed until conservative treatment has been given a satisfactory trial, they cannot reasonably be delayed until the patient has become addicted to narcotics, since relief of pain does not necessarily guarantee cure of drug addiction brought on by pain For a similar reason, the operation should be one capable of bringing maximal results with a minimum of surgery, inasmuch as repeated operations, even more than futile conservative measures, only serve to aggravate an already shattered morale

Anatomy of the Pain Pathway

The type of operation employed in any given case depends on the neuroanatomic substrate of the pain pathway from the involved area and the surgical accessibility of pain fibers, the interruption of which will banish the patient's pain without impairing other important function The following is a brief résumé of the salient anatomic factors involved

Pain impulses originating in the head enter the central nervous system chiefly by way of the trigeminal, glossopharyngeal, and upper three cervical nerves [1] Those arising from the rest of the body enter by way of the spinal nerves

Soon after entering the central nervous system, the fibers conveying pain and temperature impulses separate from those of motor power and position sense, and synapse with the second neuron of the pain pathway in the posterior gray column, whose fibers in turn cross to the opposite side where they ascend in the lateral spinothalamic tract to the thalamus

Thus, we have a neuroanatomic fact of singular clinical significance, a nerve pathway in which pain fibers for a large area are distinctly isolated from those of motor power and position sense which makes possible the relief of extensive, intractable pain without endangering other function.[2]

The emotional coloring imparted to the perception of pain appears to be a function of the frontal cortex, which is looked upon as essentially an afferent center comparable to the visual and auditory cortex [3]

Sites of Interruption of the Pain Pathway

The optimal point at which pain impulses are to be intercepted will depend chiefly on the location of the patient's pain and its extent The following types of pain-relieving procedures have proved useful

Interruption Along the First Neuron.—In general, pains in the head, neck, and trunk and those of limited distribution in the limbs may be relieved by interruption of the first neuron, i e , the peripheral nerve, sympathetic chain, or posterior root Of these, only in the case of sensory root section may regeneration not be expected to take place

Since most peripheral nerves carry both sensory and motor fibers, it is important first to make certain that such interruption will cause no significant disturbance of motor power or position sense Section of posterior roots offers no danger of motor paralysis, but if extensively carried out, as for pain in an entire limb, will leave a useless extremity because of the resulting destruction of the sense of position and movement

Head pains, such as those of trigeminal and glossopharyngeal neuralgia, for example, are more effectively relieved by interruption of pain fibers along the first neuron of the pathway for head pain, i e , by section of the sensory roots of the fifth and ninth cranial nerves, than are pains in the extremities by interruption of their corresponding posterior roots This is because position sense is not a factor to be concerned about when dealing with head pain For a similar reason, some forms of intractable visceral pain, such as that of angina pectoris, may be satisfactorily relieved by posterior root section

Spinothalamic Tractotomy—Effective relief of chronic intractable pain of wide extent can only be accomplished if pain fiber interruption is carried out more centrally, where separation from fibers subserving motor power and position sense has taken place

Such central interruption is quite commonly carried out along the second neuron of the pain pathway, namely, in the spinothalamic tract This tract may be sectioned at the high thoracic, high cervical, medullary or mesencephalic levels Of these, the high thoracic is the safest for section and the level at which operation is most commonly employed Incision there can generally be depended upon to give analgesia up to the level of the xiphoid or nipple

Despite the advanced age of the usual patient undergoing spinothalamic tractotomy and the debilitation resulting from prolonged unbearable pain, the operation is quite well tolerated Cachectic patients, who are poor surgical risks, generally are also not likely to survive long enough for spinothalamic tractotomy to be of much value, and are better treated by liberal doses of analgesic drugs

A possible complication of this procedure is transitory retention of urine, particularly if cord incisions are made bilaterally or too deeply A rare complication is lower limb weakness resulting from inadvertent incision in the region of the pyramidal pathway This tract is readily avoided, yet with effective section of the spinothalamic pathway, if the incision is confined to the area anterior to the dentate ligament and restricted to a depth of 3 mm

If the patient's pain involves the upper extremity, the spinothalamic tract must be interrupted at a high cervical level This is not consistently satisfactory because it involves greater risk to the patient, and, if pain extends as high as the neck and shoulder, the procedure cannot be depended upon to give a sufficiently high level of analgesia

The answer to the problem of high level pain may be furnished by the newly developed procedures of spinothalamic tractotomy in the medulla and midbrain [4 5] Preliminary reports to date are encouraging, and it is likely that the future will bring wider employment of these pain-relieving measures

The conditions in which spinothalamic tractotomy may be indicated include the pains of tabes, phantom limb, peripheral vascular disease, malignancy, and Paget's disease

Case 1 —The efficacy of this procedure in effecting longstanding rehabilitation is illustrated by the case of a thirty-four-year-old transit system investigator, who on February 23, 1943, underwent a gastrectomy for a lymphosarcoma of the stomach Subsequently, he developed sciatic pain and the clinical picture of a cauda equina tumor On June 6, 1947, he underwent a combined thoracic and lumbar laminectomy for an ependymoblastoma involving practically all of the conus and cauda equina The great extent of the tumor required the removal of six laminar arches The tumor itself was removed subtotally, that part of it invading the cord being left behind Postoperatively, intractable left sciatic pain persisted to such an extent that the patient could not get out of bed

Accordingly, on July 3, 1947, a right spinothalamic tractotomy was carried out This resulted in complete relief of pain and a level of analgesia on the left up to the level of the xiphoid The patient was free of pain when discharged on July 27, 1947, and at the most recent follow-up check on November 5, 1948, sixteen months following operation, was still without pain and carrying out effectively his work as a transit system investigator

Thalamofrontal Tractotomy (Prefrontal Lobotomy) —Certain types of pain occasionally fail to respond to any of these forms of treatment This is particularly true in long standing chronic pain associated with secondary narcotic addiction and personality deterioration An individual so afflicted may become free of pain but not necessarily of the drug habit following spinothalamic tractotomy Because of this and the fact that high bilateral pains require a somewhat hazardous and extensive surgery, another approach to some of these cases has been needed

As noted previously, it appears probable that the frontal cortex participates in the phenomenon of pain, particularly as regards its emotional component Although distinctly a matter apart from actual pain perception this component nevertheless plays a role in the response to pain stimuli Thus, anxiety and apprehension may influence the problem of the patient with chronic unbearable pain

This problem has in large measure been met by the relatively simple procedure of thalamofrontal tractotomy, the rationale of which is based on the modification of pain stimulus appreciation by the state of activity of the prefrontal cortex [6] The operation which, like spinothalamic tractotomy, is tolerated quite well by such patients, despite their usual poor condition, may readily be carried out under local anesthesia It involves interruption of the thalamofrontal pathway in each hemisphere in the plane just anterior to the coronal suture and the anterior horn of the lateral ventricle The approach on each side is through a trephine opening, 1 inch in diameter, placed just in front of the coronal suture Postoperatively the patient may be confused and incontinent for about two weeks, by which time, however, he is generally able to leave the hospital The optimal effect of the procedure is usually not reached until the end of a month Unpleasant late side-effects are unusual

This procedure, by freeing the patient of the affective component of his pain, enables him to endure it without mental distress Such a patient although capable of experiencing pain stimuli, actually continues to remain comfortable and cheerful More recently, it has been found that similar results may be obtained with unilateral lobotomy [7]

Although beneficial effects may result from the operation even after drug addiction and personality disintegration have set in, it is preferable to anticipate such progression and spare the patient

a period of unnecessary suffering by carrying out lobotomy before this phase is actually reached

Conditions in which other procedures may be futile and in which prefrontal lobotomy may prove useful include the pains of malignancy, causalgia, phantom limb, and postherpetic neuralgia It has also been found particularly serviceable in cases of intractable pain associated with or based upon an emotional disorder, as illustrated by the following case

Case 2—A fifty-one-year-old housewife was referred for study regarding the advisability of trigeminal sensory root section for a "pulling" pain in the right side of the mouth and face, which had been present for approximately two years and was attributed by the patient to "sinus trouble" Treatment along such lines did not bring about appreciable relief

The past history revealed a background of extensive investigation and treatment based on the diagnosis of an involutional disorder Shock therapy had been utilized, apparently without significant change

Blocking of the right posterior palatine, infraorbital, and posterior superior alveolar nerves with alcohol during the early part of 1948 resulted in an estimated "50 per cent" relief of the patient's pain

When seen on February 17, 1948, the patient continued to complain of pain and behaved in a very lacrimose manner Apart from those referable to the mental sphere, abnormal findings on neurologic examination were minimal—slight hyperesthesia in the region of the right cheek and right upper lip and exquisite tenderness on palpation of the anterior wall of the right maxilla It was felt that the condition was not of the nature of trigeminal neuralgia or sensory nerve irritation and that the pain and emotional disorder might be helped by a prefrontal lobotomy Consultation was had with a psychiatrist who felt that the patient was suffering from involutional melancholia and that, because of the duration of her illness and the rather poor response to shock therapy, not much could be gained by a repetition of this form of treatment

A bilateral thalamofrontal tractotomy was carried out on March 29, 1948, under general anesthesia On regaining consciousness the patient was moderately confused and incontinent for a period of about twenty-four hours, following which she was surprisingly alert, jocular, and convivial She no longer complained of her former pain Psychiatric re-evaluation disclosed that the patient's aggressive hypochondriasis was no longer turned against herself and that she was no longer depressed or lacrimose The patient had an essentially uneventful convalescence, and she was discharged on the sixth postoperative day

A follow-up report from her physician disclosed a continued improvement in the patient's condition Except for a tendency to be "boisterous," her mental status appeared satisfactory Seven months following operation, the patient was still essentially free of the pain that prompted the operative procedure except for an occasional twinge which did not seem to cause her anxiety as in the past She was now able to carry out her domestic duties

Applicability to Malignant Disease

Having considered the sites within the central nervous system that are accessible to surgical attack for the relief of chronic, intractable pain and having mentioned certain disease conditions in which these procedures are applicable, it would seem appropriate to place particular stress on the applicability of such measures in the treatment of the pain of malignant disease, because of its fairly common occurrence in clinical practice, its ability to cause pain in any area of the body, and because it illustrates well the pressing problem of surgical relief

The viewpoint that appears to have found general favor among neurosurgeons is to consider surgical measures for relief of such pain if medical opinion deems the patient's life expectancy too great for effective control by narcotic medication The administration of opiates with an expectancy greater than four months, for example, is likely to be fruitless because of inevitable addiction With shorter expectancy, the use of opiates in preference to palliative surgery should be considered

The following four general groups of cases of painful malignant disease may be categorized from the standpoint of surgical indications for relief

1 Pain below the level of the nipple, for which spinothalamic tractotomy at the first or second thoracic segment is the procedure of choice

2 Head pains resulting from malignancy Many of these can be relieved by section of the sensory root of the trigeminal nerve More extensive involvement will require interruption of the glossopharyngeal nerve as well. In rare cases the sensory portion of the vagus, as well as the upper cervical nerves may have to be interrupted Probably it is preferable in such instances to carry out the far less extensive procedure of thalamofrontal tractotomy Each case thus must be individualized, and the decision as to the amount and type of surgical interruption needed will depend on the preoperative assessment of the extent of the patient's pain distribution

3 Pain in the upper limb such as occurs with cancer of the breast or superior sulcus tumor involving the brachial plexus presents a fairly formidable problem Posterior root section will relieve the pain but leave a useless limb because of the loss of position sense High cervical spinothalamic tractotomy cannot be depended upon to give the high level of analgesia required for the relief of such pain The elaboration of the technic of spinothalamic tractotomy in the medulla or midbrain may ultimately provide the

answer to this specific problem At the present time thalamofrontal tractotomy appears to offer most for such patients

4 For high bilateral pain resulting from malignant disease, probably the safest and most effective procedure is a thalamofrontal tractotomy

In general, a thalamofrontal tractotomy should be considered for any patient suffering from painful malignant disease if the clinical picture is complicated by anxiety and the drug habit Since the individuals afflicted suffer not only pain, but the knowledge or lurking suspicion that their days may be numbered, it is apparent that the proper management of such patients may require more than the relief of pain Lobotomy in such cases serves the twofold purpose of enabling the patient to disregard his pain and of banishing the anxiety and apprehension associated with the underlying disease The resulting freedom from pain may occasionally permit enhancement of intellectual function, and, despite the presence of malignant disease, the general health, as manifested by weight gain, may improve

Summary

The relief of chronic, unbearable pain may be achieved by interruption at specific sites in the nervous system of nerve pathways transmitting or influencing pain impulses

The most suitable procedure for relief of extensive intractable pain below the level of the nipple is a spinothalamic tractotomy By this means the pain fibers supplying a large area can be sectioned through a small incision without concurrent damage to fibers subserving motor power and position sense

Intolerable pain in the head, neck, or trunk may be relieved by sensory root section Interruption of fibers subserving position sense does not offer a problem when dealing with pain in these areas

For high bilateral pain, pain that may require section of too many sensory roots, or pain complicated by narcotic addiction, a thalamofrontal tractotomy is probably the safest and most effective procedure In addition, it serves to banish the anxiety and apprehension that may be associated with the underlying disease

Thalamofrontal tractotomy is also of value in relieving intolerable pain associated with an emotional disorder where local or psychotherapy may fail to help

Sensory root section and spinothalamic and thalamofrontal tractotomy are pain-relieving procedures of proved usefulness, which are well tolerated by patients despite their usual advanced age and the debilitation that may result from prolonged suffering prior to operation

However, appropriate measures of this sort should be instituted before the stage of cachexia is reached, not only so that the patient may still be a reasonably good surgical risk, but also to forestall months of unnecessary suffering and the development of drug addiction

Thus, it may be expected that, if the appropriate procedure is carried out at an optimal time, not only will a gratifying relief of pain ensue for the patient but also, even if pain is due to malignant disease, the general health, as manifested by weight gain, may improve

RISKS INVOLVED IN USE OF MANY HAIR DYES

Unfavorable reactions to certain hair dyes may be due to a sensitivity which could not be predicted by present methods, says a report of the A M A Committee on Cosmetics, in the May *Hygeia*

Dyes should never be used on a scalp that has breaks in the skin and should never be permitted to get into the eyes Henna and other dyes of vegetable origin are among the safest preparations for *hair coloring* Few cases of sensitivity due to their use have been reported

Reactions to hair dyes are most often characterized by a rash of the scalp, face, and neck. A few have been reported to have caused generalized skin disturbances, disturbances of the eyes, neuralgic pain, headaches, and other complaints

Metallic hair dyes create the illusion that color is being restored to the hair and have been called "hair color restorers" rather than dyes Laboratory and clinical evidence indicates that the metallic salts that make up these dyes are not absorbed through the skin But if they should enter the blood stream through scalp lesions or through contamination of food by *hands which are not washed thoroughly* after use of the dye, the chemical may accumulate in the body and eventually cause symptoms of metallic poisoning, the committee says

THE SIGNIFICANCE OF BLOOD METHYLGUANIDINE IN POLIOMYELITIS

DOMENICO CASCIO, M D , New York City

THE resemblance between poliomyelitis and parathyroid tetany has been pointed out [1] One of the main symptoms which accounts for the similarity between tetany and poliomyelitis is the spasticity The hyperguanidinemia found in parathyroidectomized animals has been suspected of being related to this spasticity, although opinions in this respect are not unanimous Nevertheless, the hypothesis seems justified that the spasticity in poliomyelitis may be related to hyperguanidinemia, and on this basis an investigation of the guanidine content of the blood in postpoliomyelitic cases was undertaken

According to data in the literature, the methylguanidine in the blood of the normal person averages 0 20 mg per cent [2] In order to verify these figures, the methylguanidine content in the blood of 38 normal control patients and two with Parkinson's disease was determined The blood guanidine values were found to vary between 0 15 and 0 20 mg per cent Estimation of methylguanidine in the blood was done by the photometric method of Andes-Myers, described by Levinson and MacFate, which is based on the reaction of the guanidine bases with alkaline nitroprusside ferrocyanide reagent [3]

The normal values having been confirmed by this method, the blood guanidine content of 60 cases of poliomyelitis was determined (Table 1)

A statistical analysis of the results obtained in 60 poliomyelitis patients showed a mean of 0 90 mg per cent and a sigma square (square of the standard deviation) of 0 14

A further analysis of the material led to the separation of two groups (1) 43 cases in which paralysis was of the nonspastic type and (2) 17 cases which showed spasticity or deformities presumably due to spasticity

In the spastic group, the mean of the methylguanidine level is 1 15 mg per cent with a sigma square of 0 10 In the nonspastic group the mean is 0 81 and the sigma square 0 14 The difference between the means of these two groups is 3 6 times the difference of the standard error, hence, the figure is statistically significant

For further analysis the material was divided in two other groups (1) cases in which the disease had lasted for not more than two years and (2) cases which had acquired the poliomyelitis more than two years ago In the first group, there were 26 cases, and in the second group there were 34 In the first group, the mean was 0 95 mg per cent with a sigma square of 0 11 In the second group, the mean was 0 87 with a sigma square of 0 167 Thus, the difference between the two groups is statistically not significant

TABLE 1 —MATERIAL STUDIED

Case Number	Age	Duration	Diagnosis	Amount of Methylguanidine in Blood (Mg Per Cent)
1	14	8 months	Contractures of the right leg	0 90
2	8	12 months	Spastic paraplegia	1 00
3	19	18 months	Flaccid paralysis both legs	0 79
4	20	2 years	Flaccid paralysis right leg	0 50
5	12	4 years	Dropped foot	0 60
6	12	12 months	Spastic contractures of left leg and arm	1 40
7	13	3 years	Mild flaccid paralysis left leg	0 35
8	13	4 years	Paraplegia	0 75
9	15	9 months	Paresis of arms	1 30
10	12	21 months	Spastic hemiplegia	1 40
11	23	2½ years	Paresis left leg	0 88
12	11	8 months	Contractures right leg	1 30
13	14	1 year	Mild paresis right arm	0 35
14	8	16 months	Mild paresis left arm	0 35
15	13	2 years	Paraplegia (spastic)	1 48
16	6	10 months	Paresis left leg right arm	0 75
17	11	3 years	Dropped foot	0 40
18	16	5 years	Paresis of both arms	1 25
19	15	6 months	Paraplegia	1 40
20	32	4 months	Paresis left foot	0 70
21	31	3 years	Mild paresis right arm	0 40
22	40	27 years	Paraplegia with marked muscular atrophy	0 75
23	44	34 years	Paralysis left leg with marked atrophy	1 00
24	27	20 years	Mild dropped left foot	0 70
25	26	20 years	Mild paralysis right leg	0 35
26	16	12 years	Paralysis left leg right arm	1 30
27	36	21 years	Paraplegia (spastic)	1 80
28	16	2 years	Spastic paraplegia	1 00
29	12	1 year	Spastic paresis left leg	0 80
30	18	6 years	Deformities of spine	1 35
31	15	4 years	Paresis of both arms	1 40
32	17	10 years	Mild paresis left leg	0 60
33	18	12 years	Paresis right leg left arm	0 30
34	21	10 years	Serious deformities	2 00
35	10	21 months	Paraplegia (spastic)	1 40
36	21	19 years	Serious spasticity of legs	1 20
37	13	1 year	Spasticity of legs paralysis right arm	1 10
38	13	17 years	Paresis of both arms	0 90
39	15	1 year	Spastic paraplegia	1 00
40	13	2 years	Spine deformities	0 95
41	18	3 years	Paresis right leg left arm	0 35
42	5	1 year	Paresis left arm left leg	0 85
43	4	1½ years	Spastic paralysis left leg	0 80
44	12	2 years	Mild spastic paraplegia	0 90
45	15	1 year	Deformity of trunk	1 20
46	22	9 years	Dropped right foot	0 45
47	12	2 years	Flaccid paralysis left leg	0 35
48	36	20 years	Paralysis right leg (flaccid)	0 60
49	25	15 years	Flaccid paralysis left leg	0 40
50	28	15 years	Spine deformities	0 80
51	6	1 year	Paresis left arm	1 00
52	8	1 year	Spine deformities	1 20
53	28	15 years	Paraplegia	0 40
54	32	20 years	Flaccid paraplegia with advanced muscular atrophy	0 70
55	33	21 years	Paralysis left arm right leg	0 80
56	20	10 years	Paraplegia	0 95
57	25	15 years	Spine deformities	1 00
58	15	2 years	Neck deformities	1 40
59	7	2 years	Paresis right arm	0 65
60	12	5 years	Paresis right arm, left leg	0 75

Discussion

An increase in blood guanidine is not a unique phenomenon limited to cases of poliomyelitis High values have been found in tetany, spasmophilia, rickets, muscular dystrophy, eclampsia, hypertension, renal insufficiency, epilepsy, and liver damage Most of these conditions are characterized either by manifestations of convulsive seizures, as in spasmophilia, eclampsia, and epilepsy, or by muscular atrophy, as in rickets and muscular dystrophy, or by spasticity of the smooth musculature, as in hypertension Experimental work also seems to point out the spastic effect of high blood methylguanidine levels [2] Intramuscular injection of a 5 per cent methylguanidine solution into experimental animals induces convulsions, twitching, and finally death [4]

The cause of hyperguanidinemia is not certain According to MacFate, it is probable that the level of blood guanidine depends upon the activity of the centers of detoxication [5]

The formation of methylguanidine in the body is still a moot question, but it is likely that this product occurs within the muscular fibrils by means of oxidation of creatin

Disturbances of metabolism in the muscle tissue, involving the metabolism of creatinine or creatinine phosphate which might give rise to the formation of guanidine, are usually part of a systemic metabolic disorder such as hypoglycemia [6]

That hypoglycemia plays a role in the susceptibility to poliomyelitis has been claimed long ago, for susceptibility to poliomyelitis in rabbits could be induced by injections of insulin and the subsequent lowering of the blood sugar level [7] Other experimental work is in keeping with this view Monkeys, injected with the virus of infantile paralysis, if put in rotating cages and subjected to exhausting exercises develop a higher incidence and a more severe morbidity than the controls [3] It is a well-known fact that muscular overexertion can cause hypoglycemia Experimental work by Draper and Aycock has led to the belief that susceptibility to poliomyelitis is related to hormonal imbalance, and this is in keeping with clinical observations which indicate that the pituitary, surrenale, and thyroid glands are capable of influencing carbohydrate metabolism [8 9]

In view of the fact that the virus of poliomyelitis has been demonstrated in children or adults who were in contact with patients affected with this disease but who did not acquire the illness, it seems evident that the presence of the virus in the body alone is not enough to produce the disease Hence, it is necessary to postulate another factor which breaks down the natural resistance of the body and permits the virus to become actually pathogenic Epidemiologic studies show that physical overexertion, indulgence in foods rich in carbohydrates, acute infections, and liver insufficiency are likely to open the path for polio virus [3 10] All these conditions, however, by themselves or in connection with a functional disorder of the endocrine glands are likely to produce hypoglycemia

Thus, the role of hypoglycemia would be twofold first, it increases susceptibility to the disease, and second, by contributing to the higher blood guanidine level, it induces spasticity and becomes responsible for complicating features of the disease On this basis the study of preventive measures on a larger material is desirable This would include (1) restriction of outdoor exercise during the summer months in times of polio epidemics and (2) dietary measures to correct hypoglycemic tendencies

Among the early manifestations of poliomyelitis which should be combated most vigorously, spasticity ranks in the fore This can be achieved successfully by intravenous injections of calcium or of intramuscular injections of antitetanus serum which is likely to neutralize the effects of methylguanidine and thus control spasticity In 40 patients of the series reported in this paper, the injection of 20,000 units of the antitetanus serum every three hours showed a beneficial effect, especially in severe early cases.

Conclusion

The methylguanidine content of the blood was investigated in 60 cases of poliomyelitis A substantial increase was found in all cases

The blood level was particularly high in the spastic cases, the difference between the mean of the spastic and the nonspastic cases was statistically significant

The role of hyperguanidinemia in poliomyelitis is discussed and correlated with disturbances of carbohydrate metabolism

The significance of hypoglycemia for the susceptibility to poliomyelitis in experimental animals and humans is pointed out

EXPERIENCES WITH ANTICOAGULANT THERAPY

RAYMOND J BOLLER, M D , THOMAS QUIGLEY, M D , ROBERT C TARPEY, M D , and BASIL HARRIS, M D , New York City

(From the Medical Service of St Vincent's Hospital)

EVER since 1941, when Dicumarol, the active principle of spoiled sweet clover causing hemorrhagic disease of cattle, was isolated by Link and his associates at the University of Wisconsin, a new approach has been made to the treatment of thromboembolic disease [1] The following years have seen many reports in the medical literature concerning the successful use of Dicumarol alone or in conjunction with heparin in combating thrombotic emergencies Most of the work has been carried on in private institutions where control of patients and drugs and laboratory work has been under optimal conditions The patients too have been, on the whole, in good general health Because of the early unfavorable reports in the literature regarding complications, general hospitals have been reluctant to adopt this therapy as a routine procedure

Slightly over one year ago, a standard laboratory procedure (Shapiro) was adopted in the determination of prothrombin time at this hospital It was our privilege to be permitted to follow all service cases in the hospital that required the use of anticoagulants

The general procedure in administering Dicumarol is to obtain an initial prothrombin time and give 300 mg of the drug on the first day, 200 mg on the second day, and 50, 100, and 200 mg on each succeeding day, depending on the daily prothrombin result The normal prothrombin time for our laboratory is fifteen to seventeen seconds, using rabbit lung as the thromboplastic substance Twenty-two seconds represent a 30 per cent prothrombin concentration, 26 seconds a 20 per cent prothrombin concentration, and 40 seconds a 10 per cent prothrombin concentration An effort is made to keep the prothrombin time between twenty-eight and thirty-five seconds (15 to 18 per cent prothrombin concentration) When a daily prothrombin time is reported above thirty-five seconds, no Dicumarol is given, when between twenty-eight and thirty-five seconds, 50 to 100 mg are given, when the prothrombin time is below twenty-eight seconds, 100 to 200 mg may be given.

In an emergency, where an immediate anticoagulant response is required, 50 mg of heparin are given intravenously every four hours for thirty-six to forty-eight hours until the prothrombin time has reached a therapeutic level by means of concomitantly administered Dicumarol It is felt that clotting times are not necessary This is in accord with Bauer and other workers [2,3]

Material

In twelve months, 85 patients were treated with Dicumarol alone or in conjunction with heparin (Table 1) There were three deaths from pulmonary embolism One of these occurred after Dicumarol was discontinued because the patient had subacute bacterial endocarditis Another occurred in a patient with an acute myocardial infarction during the first day of anticoagulant therapy The third death occurred in an elderly, debilitated cardiac who had auricular fibrillation but was given Dicumarol because of the presence of a thrombophlebitis There were no deaths that could be directly attributed to hemorrhage

TABLE 1 —TYPES OF THROMBOEMBOLIC DISEASE TREATED WITH ANTICOAGULANTS

Venous thrombosis	45
Acute myocardial infarction	25
Peripheral arterial thromboembolic disease	7
Cerebral thromboembolic disease	4
Auricular fibrillation (conversion to regular rhythm)	4
Total	85

It is interesting to note in this series of 85 patients that the original or starting prothrombin time was over twenty seconds in 15 patients and nineteen to twenty seconds in 13 patients (our normal range being fifteen to seventeen seconds) There was no direct relationship of bleeding from Dicumarol to the original prothrombin state of any of these patients When the original prothrombin time was above our normal range, however, greater caution was used and smaller doses of the drug administered

Venous Thrombosis —There were 45 patients treated for venous thrombosis This group was composed of 17 patients having phlebothrombosis and 28 patients having thrombophlebitis Eighteen occurred in medical patients, 27 patients were nonmedical. A further grouping in the surgical specialties is illustrated in Table 2

In this series of cases of venous thrombosis, there were 21 men and 24 women

Figure 1 illustrates the distribution of cases of venous thrombosis according to age As reported by other workers, the greatest number of

Discussion

An increase in blood guanidine is not a unique phenomenon limited to cases of poliomyelitis High values have been found in tetany, spasmophilia, rickets, muscular dystrophy, eclampsia, hypertension, renal insufficiency, epilepsy, and liver damage Most of these conditions are characterized either by manifestations of convulsive seizures, as in spasmophilia, eclampsia, and epilepsy, or by muscular atrophy, as in rickets and muscular dystrophy, or by spasticity of the smooth musculature, as in hypertension Experimental work also seems to point out the spastic effect of high blood methylguanidine levels [2] Intramuscular injection of a 5 per cent methylguanidine solution into experimental animals induces convulsions, twitching, and finally death [4]

The cause of hyperguanidinemia is not certain According to MacFate, it is probable that the level of blood guanidine depends upon the activity of the centers of detoxication [5]

The formation of methylguanidine in the body is still a moot question, but it is likely that this product occurs within the muscular fibrils by means of oxidation of creatin

Disturbances of metabolism in the muscle tissue, involving the metabolism of creatinine or creatinine phosphate which might give rise to the formation of guanidine, are usually part of a systemic metabolic disorder such as hypoglycemia [6]

That hypoglycemia plays a role in the susceptibility to poliomyelitis has been claimed long ago, for susceptibility to poliomyelitis in rabbits could be induced by injections of insulin and the subsequent lowering of the blood sugar level [7] Other experimental work is in keeping with this view Monkeys, injected with the virus of infantile paralysis, if put in rotating cages and subjected to exhausting exercises develop a higher incidence and a more severe morbidity than the controls [3] It is a well-known fact that muscular overexertion can cause hypoglycemia Experimental work by Draper and Aycock has led to the belief that susceptibility to poliomyelitis is related to hormonal imbalance, and this is in keeping with clinical observations which indicate that the pituitary, surrenale, and thyroid glands are capable of influencing carbohydrate metabolism [8 9]

In view of the fact that the virus of poliomyelitis has been demonstrated in children or adults who were in contact with patients affected with this disease but who did not acquire the illness, it seems evident that the presence of the virus in the body alone is not enough to produce the disease Hence, it is necessary to postulate another factor which breaks down the natural resistance of the body and permits the virus to become actually pathogenic Epidemiologic studies show that physical overexertion, indulgence in foods rich in carbohydrates, acute infections, and liver insufficiency are likely to open the path for polio virus [2 10] All these conditions, however, by themselves or in connection with a functional disorder of the endocrine glands are likely to produce hypoglycemia

Thus, the role of hypoglycemia would be twofold first, it increases susceptibility to the disease, and second, by contributing to the higher blood guanidine level, it induces spasticity and becomes responsible for complicating features of the disease On this basis the study of preventive measures on a larger material is desirable This would include (1) restriction of outdoor exercise during the summer months in times of polio epidemics and (2) dietary measures to correct hypoglycemic tendencies

Among the early manifestations of poliomyelitis which should be combated most vigorously, spasticity ranks in the fore This can be achieved successfully by intravenous injections of calcium or of intramuscular injections of antitetanus serum which is likely to neutralize the effects of methylguanidine and thus control spasticity In 40 patients of the series reported in this paper, the injection of 20,000 units of the antitetanus serum every three hours showed a beneficial effect, especially in severe early cases

Conclusion

The methylguanidine content of the blood was investigated in 60 cases of poliomyelitis A substantial increase was found in all cases

The blood level was particularly high in the spastic cases, the difference between the mean of the spastic and the nonspastic cases was statistically significant

The role of hyperguanidinemia in poliomyelitis is discussed and correlated with disturbances of carbohydrate metabolism

The significance of hypoglycemia for the susceptibility to poliomyelitis in experimental animals and humans is pointed out

per cent in whom the cause of death could not be specifically ascertained. With the knowledge drawn from our autopsied series of myocardial infarction, it seems fair to assume that a large part of the 36 deaths in the clinical group were due to thromboembolic complications.

Unfortunately, thus far only 25 cases of myocardial infarction have been treated by anticoagulants during their hospital course. In the beginning of our study only the more serious cases were given Dicumarol, the feeling being that these cases were entitled to every available form of therapy. The trend, however, in the last six months throughout the country has been that all myocardial infarctions will be benefited by the administration of Dicumarol during their hospital stay. That is the course which we hope to follow in the future and shall subsequently report.

All of the 25 cases of myocardial infarction presented typical histories of an acute episode, and the subsequent course, clinical findings, and laboratory data, including electrocardiograms, confirmed the diagnosis. One patient had a pulmonary embolism twenty-four hours after the myocardial infarction and before Dicumarol was effective. The patient had no further thrombotic complications and survived. Another patient had a pulmonary embolism on the fourth day of his illness and the first day of anticoagulation (heparin and Dicumarol). He expired as a result of this episode. Unfortunately, no postmortem examination was obtained. No other thromboembolic complications were encountered in these 25 cases, the percentage of thromboembolic complications being 4 per cent. Seven (28 per cent) of the patients died. Four of these were autopsied, and no evidence of mural thrombi or peripheral thrombi was noted. Since anticoagulant therapy was not employed in every established case of coronary thrombosis during the year, we feel our mortality rate is unduly high.

There were two instances of gastrointestinal bleeding in these 25 cases, one in a patient having a previously diagnosed peptic ulcer and the other in a patient having Laennec's cirrhosis. Therapy adequately controlled the bleeding in the first case. No active measures were undertaken for the second patient. The outlook was entirely hopeless. Autopsy revealed a massive anterior wall myocardial infarction with septal involvement, tiny ulcers of gastric mucosa, and tarry stool in the intestines.

Heparin was used in conjunction with Dicumarol in only three cases of myocardial infarction. Its necessity in these cases is questionable. The work of Mallory placed the usual development of mural thrombi following myocardial infarction on the sixth postinfarction day.[11] His studies further showed the sixteenth postinfarction day as the time when the mural thrombus is probably organized. It is interesting though that the only pulmonary emboli encountered in this series occurred on the first and fourth days after the onset of the acute myocardial infarction.

Cerebral Thromboembolic Disease.—In the past year, four cases of cerebral thromboembolic disease were treated with Dicumarol. Three of these were cerebral emboli occurring in patients who had auricular fibrillation. The fourth patient was a hypertensive who had suffered an earlier left cerebral thrombosis and two weeks later developed a left hemiplegia. Dicumarol was administered for two weeks with excellent result, the left side of the body regaining function on the fourth day of therapy.

In all of these cases, the presence of cerebral hemorrhage was excluded by history, clinical course, and lumbar puncture. The advisability of the use of anticoagulants in cerebral thromboembolic disease must await further trial, especially since a normal lumbar puncture may be obtained in the presence of cerebral hemorrhage.

thrombotic emergencies occur beyond the fifth decade with the greatest incidence in the seventh decade [4] The majority of the nonmedical patients experienced venous thrombosis between the fifth and fifteenth postoperative days

Our results with anticoagulants have been most successful In the 45 patients treated for venous thrombosis, ten had suffered pulmonary emboli before anticoagulants were administered After anticoagulation was started, there were three instances of embolization, two of which were cited above It was felt in the first case that, because of the presence of subacute bacterial endocarditis and its known tendency to cause spontaneous hemorrhagic phenomena, the drug should be discontinued Autopsy examination of the second case of venous thrombosis, which had also had auricular fibrillation, revealed a large thrombus in the right auricle, the probable site of the fatal embolus The third instance of embolism was cerebral The patient received Dicumarol for a deep vein thrombosis The patient also had arteriosclerotic heart disease with auricular fibrillation The latter condition was undoubtedly responsible for the cerebral accident Dicumarol therapy was continued without any further misfortune in this case Two instances of hemorrhagic complications were encountered One patient developed gross hematuria at a time when the prothrombin time was sixty-six seconds Vitamin K was administered intravenously in 72-mg doses at four-hour intervals, and the urine was grossly clear in twenty-four hours Dicumarol therapy was continued without further incident A second patient with a venous thrombosis of the deep veins of the leg developed a large hematoma along the medial aspect of the affected thigh. A review of her history, hospital course, and laboratory studies disclosed a vitamin C deficiency The latter was administered along with anticoagulants without any further trouble.

Vitamin K was administered on three occasions to patients having extremely high prothrombin time, in whom hemorrhage was thought to be more likely to occur On several occasions in these cases of venous thrombosis, occasional to ten red blood cells were reported in the microscopic urine analyses No active measures were taken in such instances

It is interesting to note that one of the cases of venous thrombosis was a twenty-three-year-old prenatal patient She developed a phlebothrombosis with subsequent benign pulmonary embolism This occurred in the fifth month of pregnancy Anticoagulants (heparin and Dicumarol) were administered successfully

Myocardial Infarction.—The interesting reports of Peters, Barker, and Wright on the use of anticoagulants in the treatment of myocardial infarction have certainly given hope for the future that fatal pulmonary embolism and venous thromboses, which often complicate this clinical state, may be prevented [5–7] The literature is replete with statistics showing the incidence of mural thrombi, pulmonary emboli, and arterial and venous thrombosis complicating acute myocardial infarction The incidence of mural thrombi in myocardial infarction is especially high, the estimates varying from 17 to 83 per cent [8–10]

A review of 100 consecutive autopsies of patients having had coronary thrombosis with myocardial infarction at this hospital prior to institution of anticoagulant therapy showed a 45 per cent incidence of mural thrombi, 35 per cent of which were left-sided and 10 per cent right ventricular Twenty per cent of these patients had pulmonary infarction Figure 2 clearly illustrates this analysis

The postmortem incidence of thromboembolic disease complicating myocardial infarction is striking Almost equally significant is a review of the occurrence of thromboembolic phenomena in myocardial infarction, as seen clinically One hundred cases of clinically diagnosed myocardial infarctions, prior to institution of anticoagulants, confirmed by electrocardiographs and the usual diagnostic aids, were reviewed Fourteen of these patients developed thrombotic complications clinically detectable (Table 3) Eight of these patients died as a result of these complications The mortality of these 100 cases of myocardial infarction was 36 per cent, leaving 28

RATIONAL THERAPEUTICS OF INTESTINAL OBSTRUCTION IN INFANCY

D H Manfredi, M D , New York City

(From the Children's Surgical Service, Bellevue Hospital)

AMONG the most urgent emergencies occurring in infancy, there are few that require more rapid surgical attention than cases of acute intestinal obstruction Disturbances in the anatomy and delicately balanced physiology of an infant occur with such accelerated speed that the threat to life is forever present

In this review of 55 cases of intestinal obstruction occurring in infants under two years of age, the primary cause of the condition was an incarcerated hernia All the infants were admitted to the Children's Surgical Service of Bellevue Hospital Rational therapeutic procedures in the treatment of these lesions are based on a knowledge of the disturbed physiology which the obstructive lesion creates This paper will discuss the treatment to eliminate the obstruction and the correction of the physiologic disturbances

Intestinal obstruction has been defined as a condition in which there exists a cessation of the normal forward motion of intestinal contents long enough to produce local and systemic pathologic effects The condition may be produced by occlusion of the intestinal lumen, diminution of peristalsis, or interference with blood supply One of the aforementioned conditions or combinations of them always exists in cases of intestinal obstruction *Once stasis occurs intestinal* distention follows

This distention is due to an accumulation of gas and fluids in the obstructed portion of bowel The gas originates from three sources—from the gaseous interchange from blood flowing through the thin wall, from the action of bacteria in the intestinal contents, and from swallowed air The fluid contents come from ingested fluids, the secretion of intestinal glands, and from the fluid fraction of blood

Distention is a powerful stimulus to transudation from the blood into the bowel There results a loss from the circulating blood of its salts, fluids, water, plasma and its constituents, and chlorides The tissue spaces, or extracellular reservoir, must then give up their fluids to restore the circulating blood volume

The water requirements of an infant are 100 to 150 cc per Kg of body weight The water needs are greater than in an adult due to the poor concentrating ability of the immature kidneys, the greater metabolic requirements due to a larger surface area per unit of body weight, and factors of growth activity From Fig 1, it can be seen that the extracellular fluid is easily depleted in an infant, because it is only twice the daily total intake An adult has a great deal more in reserve, almost seven times his total daily intake Almost as important as fluid loss is the disturbance in acid-base balance When the kidney excretes an excessive amount of sodium ion, a proportionate amount of water must be excreted, further dehydrating the tissues If the interstitial reservoir of fluids is exhausted, depletion causes dehydration and death Emesis, which is related to the intestinal distention and caused by reflex and mechanical factors, causes the infants to lose not only the fluid that they should be imbibing but also that fluid and electrolyte in the vomitus

Symptoms of dehydration depend upon the rapidity with which it occurs and the relative loss of water and salts When the change is rapid, an increase in the viscosity of blood takes place with concentration of both cellular and protein elements, and there is no time for compensation for the diminution in blood volume Death may occur solely from a reduction in body fluids and salts

From the age distribution chart, it can be seen that over *fifty* per cent of this series of cases occurred in the early months of life (Table 1) This fact may give rise to the belief that herniation through a relatively narrow opening at the site of the internal ring offers greater opportunity for incarceration and obstruction than does herniation through a wider gaping internal inguinal ring Tables 2 and 3 indicate the

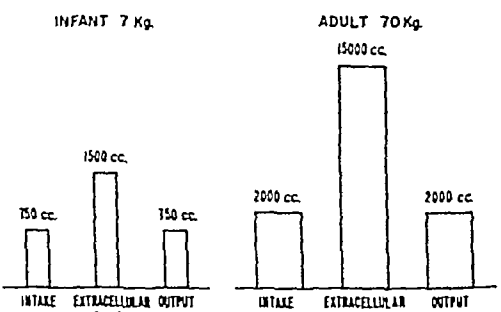

FIG 1 Average daily fluid intake and output

Peripheral Arterial Thromboembolic Disease—There were seven cases of peripheral arterial thromboembolic disease in this series Four of this group had emboli to a lower extremity The emboli were probably from the left auricle, since the four patients had auricular fibrillation—three on a rheumatic basis and the other an *arteriosclerotic cardiac* The extremities in each case were saved by medical treatment

The remaining three patients in this group had arterial occlusions, apparently on a thrombotic basis, associated with infection Two of these patients required subsequent amputation Anticoagulant therapy was administered postoperatively without further thrombosis The *third patient of this group* was an elderly man who suffered multiple fractures of both lower extremities and pelvis He succumbed of congestive heart failure after about one week of heparin therapy

Arterial Thromboembolic Emergencies and Auricular Fibrillation—Our procedure in treating arterial thromboembolic emergencies follows the same general pattern advocated by Allen [12] As soon as the diagnosis is made, a paravertebral block is performed, and blood is drawn for a prothrombin time, Heparin is administered immediately intravenously and continued every four hours, until the prothrombin time is influenced by Dicumarol If, however, no appreciable success is noted after the paravertebral block and heparin administration, surgery for embolectomy is contemplated Papaverine is also administered along with other supportive measures

In this group there was one case of bleeding due to Dicumarol Gross hematuria was noted when the prothrombin time was eighty-five seconds, vitamin K was given intravenously every four hours for four doses Twenty-four hours later, the prothrombin time was twenty-eight seconds and the urine grossly clear

Dicumarol has also been administered by us to patients having auricular fibrillation in whom conversion to regular rhythm was attempted Thus far, five patients have received anticoagulants in this process One patient developed a right hemiparesis, and the quinidine was stopped The remaining four patients were converted from fibrillation to regular rhythm without embolic mishap Further investigation is necessary to determine the value of Dicumarol in conversion from auricular fibrillation to regular rhythm, however

Full dosage of Dicumarol should be curtailed and the drug probably not given in the presence of hepatic disease, renal insufficiency, and poor nutritional state Anticoagulant therapy is contraindicated in multiple stage operations, ulcerative diseases, recent brain or spinal cord operations, and blood dyscrasias

From our observations in the past year anticoagulant therapy has its place in any general hospital, provided the laboratory standards are reliable The wide variety of patients encountered on a general service makes one doubly cautious of bleeding complications, since many patients will have abnormal initial prothrombin times Despite this, there is no reason to withhold anticoagulants provided adequate supervision is maintained

Summary

1 Experience with the use of anticoagulant therapy in 85 cases in a general hospital is presented

2 General measures in the control of Dicumarol and heparin are discussed

3 Forty-five cases of venous thrombosis were treated Ten of these patients had pulmonary emboli before anticoagulation was started One instance of fatal pulmonary embolism occurred while on Dicumarol. This patient also had auricular fibrillation, and postmortem examination revealed a large thrombus in the right auricle

4 One hundred clinical cases of myocardial infarction were studied, and the incidence of thromboembolic complications were compared with 100 in which the diagnosis was established postmortem Both groups were in the preanticoagulant period

5 Twenty-five cases of myocardial infarction treated with anticoagulants were reviewed In these cases only one death occurred from embolic complication and that on the first day of anticoagulant therapy No other thromboembolic complications were encountered

6 Seven cases of peripheral arterial thromboembolic diseases were treated

7 The treatment in cerebral thromboembolic disease and auricular fibrillation is discussed Further investigation in these fields is indicated to evaluate properly the efficacy of anticoagulant therapy for these conditions

location of the hernias and the contents of the hernial sacs at operation

There were 48 cases, or 82 per cent, that had a history of a previous mass being present before incarceration occurred Any case with a history of a previously existing hernia that develops pain and emesis must be suspected of an early intestinal obstruction due to an incarcerated hernia Vomiting occurred in 92 per cent of the total number of cases and should call for investigation of the inguinal rings

There were no cases in which the intestine per se had become necrotic However, two appendices had become necrotic, and an appendectomy was performed during the herniorraphy

One tube and ovary became gangrenous when entrapped in the hernia and required resection A part of the omentum became gangrenous in one case when it became incarcerated in the hernia sac

No case was reduced following gentle taxis which was tried in 48 per cent of the cases One case reduced spontaneously during the administration of the anesthetic

There were four postoperative deaths in this series One infant with an incarcerated umbilical hernia died postoperatively at five days of age One infant with right inguinal hernia died of status lymphaticus One infant with right inguinal hernia died postoperatively of scarlet fever, and one infant with a left inguinal hernia died of postoperative pneumonia

The operation performed prior to 1927 was a Bassini type of repair The most common technic used at present is the high ligation of the hernia sac with no plastic repair of the canal Cotton or silk suture material is used The correction of the infant's fluid balance preoperatively is stressed, and lastly, gentleness, patience, and surgical skill must be exercised in handling the delicate tissues

Summary

The importance of restoration of the physiologic fluid and electrolyte balance is emphasized Any organ in the peritoneal cavity may become entrapped in an irreducible hernia sac Rapid surgical attention to correct the disturbances in the chemical status of the infant and elimination of the obstructive lesion are the rational therapeutic procedures necessary in treating infants with acute intestinal obstruction

"It really doesn't matter," she replied "My husband never drinks water, and the dog can't read"—*Exchange*

THE INCIDENCE OF VALVULAR HEART DISEASE IN PEOPLE OVER FIFTY AND PENICILLIN PROPHYLAXIS OF BACTERIAL ENDOCARDITIS

PAUL LICHTMAN, M D , Washington, D C , and ARTHUR M MASTER, M D , New York City

(From the Cardiographic Department, Mount Sinai Hospital)

FOR some time it has been recognized that subacute bacterial endocarditis may develop in persons with rheumatic or congenital heart disease following operative and diagnostic procedures such as tooth extraction and cystoscopy With the advent of sulfonamides and, more recently, penicillin, it has become routine to administer the antibiotic to persons with such heart disease prior to and following manipulation [1-4] This method has usually been reserved for patients with obvious rheumatic or congenital heart disease, most of whom are in the younger age groups However, the problem is actually much greater since it is becoming increasingly evident that subacute bacterial endocarditis often occurs in persons over the age of fifty and in persons in whom disease is present but not obvious [1 5,6] This is indicated by recent autopsy studies which have shown a surprisingly high incidence of valvular lesions, rheumatic and sclerotic, in older persons Clinically this valvular disease is often evidenced by a loud, blowing apical systolic murmur, although the remainder of the cardiac examination is not infrequently negative

This study was undertaken with a threefold purpose (1) to determine the incidence of valvular damage in older age groups, clinically and pathologically, (2) to consider the advisability of administering penicillin to elderly persons undergoing various diagnostic and operative procedures when valvular disease is suspected, and (3) even routinely when heart disease is not believed to be present

In the older age group it is occasionally difficult to determine the etiologic background of valvular disease, that is, to distinguish between rheumatic and Monckeberg or arteriosclerotic lesions [7-13] The latter usually attacks only the aortic valve, the mitral valve being involved infrequently In favor of a rheumatic etiology is the presence of stigmata of an extinct rheumatic process such as endocardial thickening, increased vascularity of the subendocardium, increase of endocardial smooth muscle, vascularization and thickening of the valves, fusion at the aortic commissures, formation of collagenous plaques at the line of closure, and evidence of pericarditis [11] In favor of an arteriosclerotic lesion is the finding of atheromatous plaques with calcification in the absence of the above changes This is particularly true in isolated lesions of the aortic valve and ring without mitral valve changes The pathogenesis of calcific disease of the aortic valve has been a moot question in numerous investigations, but the recent study of Karsner and Koletsky would seem definitely to place it, with few exceptions, among the sequelae of rheumatic fever [14] This may also be true of other valvular lesions not obviously rheumatic in origin

In order to determine the incidence of valvular lesions in older persons, figures were compiled from necropsy protocols at the Mount Sinai Hospital in 406 consecutive patients, fifty years of age and older (Table 1) The criteria noted above were utilized in determining rheumatic or arteriosclerotic etiology [11-13] Anatomic evidence of heart disease was noted in 342 cases Rheumatic lesions were present in 176 cases (51 5 per cent) and arteriosclerotic heart disease was predominant in 133 cases (38 9 per cent) The remainder included three cases of congenital, three syphilitic, seven pulmonary, six hypertensive, and 14 miscel-

aneous heart disease In these 342 cases with heart disease, valvular damage was present in more than half the patients

Of the 234 instances of valvular heart disease, 176 were rheumatic (75 per cent), 47 arteriosclerotic (20 per cent), and 11 were grouped as miscellaneous In the rheumatic cases the mitral valve only was involved 70 times, the aortic valve only twice, and both valves in 90 cases (Table 2) The mitral and tricuspid valves were altered in four cases and the mitral, aortic, and tricuspid valves in five Five cases of minimal lesions of the mitral leaflets (thickening at the line of closure) were included because of other evidence, such as involvement of the chordae tendineae or lesions of the left auricular wall The damage in the remainder of valvular lesions varied from marked thickening of the valves to all of the usual manifestations of chronic rheumatic valvulitis

The mitral valve was thus involved 196 times or almost half (48 per cent) of the entire 406 cases studied This points to the significance of an apical systolic murmur in persons in the older age group, as has been stressed by Master who is of the opinion that unless disproved a loud blowing systolic apical murmur is indicative of an organic lesion [15,16] Furthermore, a valvular lesion may be present without producing a murmur While rheumatic valvular disease is the commonest precursor of bacterial endocarditis, it has been shown clinically and experimentally that the latter may occur in other types of valvular lesions in the presence of bacteremia [2 17-19] These include sclerotic degenerative changes in the valve and those following coronary occlusion, as well as nonbacterial collagen and thrombotic alterations

In the 47 cases of arteriosclerotic heart disease with valvular lesions, features other than rheumatic predominated, or a rheumatic etiology could not be ascertained The mitral valve alone was involved in two cases, the aortic valve alone in 32 cases, and both in 13 cases

In view of the high incidence of valvular damage in older persons, it is obvious that they are susceptible to the development of bacterial endocarditis in the presence of bacteremia Zeman and Bayles and Lewis found pre-existing rheumatic heart disease in approximately 60 per cent of their cases of subacute bacterial endocarditis over forty [1 6] In the remaining cases, arteriosclerotic, luetic, congenital, or thyrotoxic heart disease was present

Pursuing the subject of the etiologic substrata of subacute bacterial endocarditis, we reviewed 20 cases of this disease in patients over fifty years old Nine showed previous rheumatic disease seven of these on postmortem examination. Six other cases were considered arteriosclerotic on clinical grounds, although a rheumatic basis could not be definitely excluded in the absence of pathologic study In one case syphilitic, in one case congenital, and in two instances undetermined types of heart disease were found In the last case no evidence of previous disease was present

We then studied the background of 11 cases of acute bacterial endocarditis in patients over fifty years of age Six presented chronic rheumatic heart disease, and in two arteriosclerosis was present In two cases there was no pre-existing heart disease, and in one case heart disease of undetermined origin was found As these figures show, acute bacterial endocarditis occurs more frequently on previously normal valves than does subacute endocarditis

Analyzing our results, it has been shown that in 406 consecutive autopsies in patients over fifty years of age, heart disease was present in 342 and valvular damage in 234 Thus, in more than half the patients valvular disease was found, a possible nidus for subacute bacterial endocarditis This leads us to an investigation of the operative procedures which may predispose to infection of the valves.

In investigating the procedures that may produce transient bacteremia and thus may precipitate endocarditis, foci of infection in the upper respiratory tract and mouth were found to be the most common portal of entry The transient bacteremia accompanying surgical procedures in this area is not always adequately handled by the body's defense mechanisms There are numerous reports of subacute bacterial endocarditis

following tonsillectomy, infection of the nasal sinuses, otitic infections, general colds," extraction of teeth, and even chewing [2-7]

A number of other conditions have been reported as providing a portal of entry for the development of subacute bacterial endocarditis. Among these are wound and skin infections such as phlegmons and carbuncles, incised furuncles, glandular inflammations, toe infections, bone trauma and osteomyelitis, thrombophlebitis, and Raynaud's disease [2 3 5] Kidney infections and prostatic massage have been mentioned as predisposing factors [2 6] In fact, as recently reported by Baehr and Gerber, surgical and diagnostic procedures of the genitourinary tract are rather frequent precursors of infectious endocarditis [3] There has been mention of pelvic inflammatory disease and postpartum infection [22 9 9] Cancer of the lung and bronchial infection have been noted as significantly preceding the development of subacute bacterial endocarditis [23 25] The gastrointestinal tract as a portal of entry has been discussed by Horder [21] Transient bacteremia has been noted in animals after a high fat meal, and as reported by Crohn and Schwartzman, bacteria of many sorts may pass through the intestinal mucosa during digestion of fatty substances and are present in the chyle and in the blood for a few hours [22] Cancer of the stomach, infection of the gallbladder, acute gastroenteritis and surgical procedures of the gastrointestinal tract contribute to the development of subacute bacterial endocarditis [2 4 9 22 23]

To study the factors predisposing to the development of infectious endocarditis, 321 clinical records of patients with this disease were reviewed. Instances beginning with fever, malaise, fatigue, nasopharyngitis, chills and other nonspecific manifestations or those whose primary manifestations were embolic were not included. Seventy-seven cases were of special interest in that the onset of the disease could reasonably be related to a known factor. Of these 77 cases which were thus selected, 57 had subacute bacterial endocarditis and 20 the acute variety. In the 57 patients with subacute bacterial endocarditis, 30 operative and 27 diagnostic instrumental or manipulative procedures were related to the onset of the disease (Tables 3, 4, 5)

Table 3 presents the operative procedures which predisposed to the development of subacute bacterial endocarditis in 30 cases. Preexisting heart disease and organisms cultured in each case are also indicated thereon. Dental extractions preceded 12 cases. Genitourinary operative procedures were responsible for six cases. Nose and throat operations other than tonsillectomy preceded four cases. There was one case of operation for perineal ulcer and one cholecystectomy. Eight of the cases listed above were intra-abdominal operative procedures.

Of the remaining 27 cases of subacute bacterial endocarditis in which the disease could be related to an ascertainable factor, there were eight that followed an instrumental diagnostic procedure (Table 4). Bronchoscopic examination was apparently responsible for one of these cases, colonic irrigation and barium enema in a case of diverticulitis preceded another, and sigmoidoscopy was followed by development of subacute bacterial endocarditis in a third. There were five cases following cystoscopy, a fact previously stressed by Baehr and Gerber [3] The important

70	Cystoscopy and prostatectomy	Coronary artery	Bacillus proteus
52	Cystoscopy	Type undetermined	Enterococcus

factor to be noted, however, is that any diagnostic instrumental procedure that may traumatize a mucosal surface exposed to bacteria may facilitate the entrance of an organism to the blood stream with the possibility of development of infectious endocarditis. There were 19 cases in which the subacute bacterial endocarditis developed in conditions other than operations or instrumental diagnostic procedures (Table 5). There were six cases following manipulation such as "cleaning the teeth." There were four cases in the obstetric and gynecologic classification, two occurring during pregnancy and two others with pelvic infections. There were three cases with a history of gastrointestinal complaints of two to five years duration, one case of acute enteritis after overindulgence of food, and one case of acute enteritis with mushroom poisoning and apparently no other predisposing factor. In the remaining four cases in this group of 19, the subacute bacterial endocarditis followed a generalized nonpruritic papular eruption caused by neoarsphenamine, a severe, generalized attack of urticaria, traumatic bone injury, and German measles.

The 20 cases of acute bacterial endocarditis were similarly classified as to portal of entry of the precipitating organism. There were nine surgical procedures (three of which were intra-abdominal), two instrumental diagnostic manipulations, one case following the passage of a urethral sound, four cases of acute enteritis, one case with infection of the leg (thrombophlebitis?), two cases of acute sinusitis, and one case of cancer of the liver.

It is thus apparent, both from the literature and the cases we have presented, that all types of operations and diagnostic procedures may facilitate the passage of micro-organisms into the blood stream with development of infectious endocarditis.

Since we have indicated that valvular damage is so common in people over fifty and since operative and diagnostic procedures produce a bacteremia which may invade a damaged valve and result in infectious endocarditis, it is natural to inquire which prophylactic measures are indicated in order to prevent subacute and acute bacterial endocarditis in people over fifty.

The prophylaxis of subacute bacterial endocarditis has been greatly enhanced by the availability of penicillin because of its bacteriostatic and bactericidal power against the organisms usually responsible for this disease. Prior to the introduction of penicillin the use of sufonamides was advocated in patients with rheumatic heart disease before tooth extraction and tonsillectomy because of the transient bacteremia frequently encountered in such procedures. More recently, the prophylactic use of penicillin alone or in conjunction with the sulfonamides in such procedures in rheumatics has been advocated by Flippen and Van der Veer.[21,34] Recognition of the possibility of reinfection in healed cases of subacute bacterial endocarditis has prompted removal of foci of infection in such cases before

TABLE 5.—Nineteen Cases of Subacute Bacterial Endocarditis Following Conditions Other Than Operations or Diagnostic Procedures

Age	Predisposing Condition	Heart Disease	Organism
30	Dental manipulation (no extraction)	Rheumatic	S. viridans
46	Dental manipulation (no extraction)	None (?)	S. viridans
37	Dental prophylaxis (gingivitis)	Rheumatic	Negative culture (autopsy)
23	Dental prophylaxis (gingivitis)	None (?)	Pleuropneumonia like
38	Dental prophylaxis (gingivitis)	Type undetermined	S. viridans
49	Malocclusion of teeth and trauma	None	Gram positive cocci pneumococcus
33	Pregnancy	Rheumatic	S. viridans
29	Pregnancy	Congenital	No culture
21	Infection of vulva	Rheumatic	S. hemolyticus
14	Infection of vulva	Congenital	S. viridans
52	Gastrointestinal complaints 5 years	Congenital	No culture (autopsy)
36	Gastrointestinal complaints 2 years	Rheumatic	Bacteria free
50	Gastrointestinal complaints, 4 years	Rheumatic	Bacteria free
55	Acute enteritis	Type undetermined	S. viridans
71	Acute enteritis mushroom poisoning	Coronary artery	S. viridans
26	Generalized urticaria	Rheumatic	Gram positive cocci
26	Following german measles	Rheumatic	S. viridans
19	Bone bruise	Rheumatic	S. viridans
21	Nonpruritic papular eruption	Rheumatic	S. viridans

they are permitted to leave the hospital. Loewe has advocated the removal of infective foci in the upper respiratory tract and of diseased teeth in healed cases of subacute bacterial endocarditis, with administration of penicillin before and after such procedures.[25] Davis has called attention to the fact that the eradication of foci of infection in the pharynx is not accomplished merely by removal of the tonsils.[26] Adenoids, lymphoid tissue on the posterior pharyngeal wall, and particularly the lingual tonsils are frequent undetected foci of infection. Baehr and Gerber have proposed the administration of penicillin immediately prior to procedures such as cystoscopy and removal of teeth in patients with rheumatic heart disease and in arrested cases of bacterial endocarditis.[3] They further suggested that penicillin should be continued for twelve to forty-eight hours following such procedures.

In our series of 57 cases of subacute bacterial endocarditis in patients over fifty years old in which an operative, diagnostic, or other procedure was discernible, the blood culture was positive in 50 cases (Tables 3, 4, 5). An organism considered usually susceptible to penicillin was found in 42 cases, in six of the remaining eight, enterococci were found. Since the bacterial invader in most cases of subacute bacterial endocarditis is usually susceptible to penicillin, this agent should obviate the development of the disease in some cases. We believe that a patient with a history of rheumatic fever, a loud systolic murmur, or other signs or symptoms of heart disease should receive penicillin before and after operations or in instrumental diagnostic procedures. Such prophylaxis may also prevent acute bacterial endocarditis. In the 20 cases of acute bacterial endocarditis there were five with organisms considered usually not susceptible to penicillin. A negative culture was obtained in three cases. In 11 cases, however, the bacterial invader was susceptible to penicillin. Altogether, then, in the 77 cases of subacute and acute bacterial endocarditis following operations, diagnostic procedures, and other conditions mentioned, organisms susceptible to penicillin were cultured in 53 cases.

At present, one can only speculate as to how many cases of infectious endocarditis may be avoided with the prophylactic administration of penicillin. Recent articles by Baehr and Gerber and Finland discuss penicillin dosage in excellent detail.[3,33] Brief mention of prophylactic dosage as suggested by Schwartzman will be made here.[27] In the absence of a known infected focus in minor operations and in dental extractions, the recommendation of the committee on chemotherapy of Mount Sinai Hospital may be followed:

> Patients who have had rheumatic fever, with or without evidence of cardiac disease, should receive 200,000 units (children should be given 100,000 units) intramuscularly, twenty minutes before a dental operation. One dose of 100,000 units should be given within thirty minutes following dental operation, three additional intramuscular injections of 100,000 units should be given at eight-hour intervals thereafter.

While this rule was devised especially for persons with probable rheumatic valvular disease who were to undergo dental operations, the same system of dosage is applicable to any person having a systolic murmur or evidence of heart disease who is to undergo a surgical or instrumental diagnostic procedure. The senior author (A. M. M.) has followed this rule for a number of years. Prior to a major operation infected tissues should first be treated with penicillin. In major operations not complicated by an infected focus a prophylactic injection of 300,000 units should be administered on the operating table immediately prior to operation. The postoperative schedule previously mentioned should be adhered to in the absence of evidence of infection following operation. However, manifestations of postoperative infection indicate an immediate increase in dosage of penicillin, depending on the susceptibility of the organism to penicillin and the severity of the infection.

Because of the occasional occurrence of moderately prolonged bacteremia following cystoscopy, penicillin should be continued for two to four days and for a longer period should there be evidence of infection.

Although nasopharyngitis, tonsillitis, bronchitis, and "colds" are among the commonest conditions preceding subacute bacterial endocarditis, they have not been included in this study. We believe, however, that a patient with symptoms or signs of heart disease should receive penicillin prophylaxis in the course of a severe upper respiratory infection.

In view of the high incidence of some degree of valvular disease found postmortem in older age groups and the frequent absence of clinical evidence of such involvement, the advisability of routine administration of penicillin prior to operation and diagnostic procedures in all persons over the age of fifty must be seriously considered.[10] In our series of 406 patients, 234 showed a valvular lesion at autopsy while cardiac examination during life was negative in 69. Although a diagnosis of heart disease could not be made during life in these latter cases, they were actually susceptible to bacterial endocarditis. The objections to the routine use of penicillin are the small percentage of cases of subacute and acute bacterial endocarditis which occur, the occasional appearance of severe sensitivity reactions to the

drug, and the fact that some organisms causing endocarditis are not susceptible to it This problem requires further consideration

Summary

In 406 consecutive autopsies in patients fifty years old or more, 342 (84 2 per cent) disclosed evidence of heart disease Rheumatic lesions were present in 176 (51 4 per cent), arteriosclerotic in 133 (39 0 per cent), and a miscellaneous group in 33 (9 6 per cent)

There was evidence of gross valvular damage in 234 hearts, that is, in more than half the cases The valvular lesions were rheumatic in 176 instances (75 per cent) and arteriosclerotic in 47 (20 per cent)

The mitral valve was involved 196 times (48 per cent of the total autopsies) This adds significance to the not infrequent finding of a blowing, apical systolic murmur in people over fifty Heart disease is very common in such persons although it may not be obvious clinically

Twenty cases of subacute and 11 cases of acute bacterial endocarditis are described in patients fifty years old or more Rheumatic, arteriosclerotic, syphilitic, and congenital heart disease were present in that order of frequency

It has been indicated that any type of heart disease, particularly valvular, which produces damage of endocardial tissues may predispose to subacute or acute bacterial endocarditis during postoperative bacteremia

Fifty-seven cases of subacute and 20 cases of acute bacterial endocarditis following operative, diagnostic instrumental, and manipulative procedures are described

A vast variety of manipulations and diseases which injure mucous membrane and facilitate the entrance of bacteria into the blood stream may lead to bacterial endocarditis in the presence of valvular disease These include infections and operations in the ear, nose, and throat, tooth extraction, bronchoscopy, genitourinary infections, operations, and procedures, infections of the pelvis, skin, gastrointestinal tract, and bone, thrombophlebitis, pneumonia, and the exanthemata Such minor conditions as a cold, prostatic massage, enteritis, and toe infection have preceded bacterial endocarditis

In 17 per cent of the patients past the age of fifty, examination of the heart was negative clinically although valvular involvement was found postmortem

Since valvular lesions are very common in persons over fifty, although often not obvious clinically, penicillin prophylaxis prior to operation and diagnostic or manipulative procedures may be instituted to obviate the development of bacterial endocarditis The dosage and method are described

---

We wish to thank Drs. George Baehr Paul Klemperer and Gregory Schwartzman for their helpful criticisms

ERYTHROBLASTOSIS FETALIS DUE TO BLOOD GROUP A-B-O INCOMPATIBILITY

LESLIE HUGHES TISDALL, M D , F A C S , and EDWARD T HARTNETT, A B , Brooklyn, New York

(From the Department of Obstetrics and Gynecology, St Catherine's Hospital)

AS DISCUSSED in a previous paper, erythroblastosis fetalis may be caused by incompatibilities existing between mother and infant not only of the Rh factor, subgroups of the Rh factor, and the Hr factor, but also of the A-B-O blood group [1] Polayes was among the first to show the relationship of erythroblastosis with A-B-O incompatibility between mother and fetus [2]

Thus a group A baby, born of a mother of blood group O whose serum contains a high titer of anti-A isoagglutinins, may have erythroblastosis due to the action of the maternal anti-A agglutinins on the fetal group A red cells Similarly, a group B baby may develop erythroblastosis due to a high titer of maternal anti-B isoagglutinins

Since erythroblastosis due to this type of blood incompatibility is caused by a high titer of maternal anti-A or anti-B isoagglutinins, this syndrome cannot occur in an infant born of a group AB mother or in an infant of blood group O There are no anti-A or anti-B isoagglutinins in group AB serum, and because group O red cells do not possess the agglutinogens A or B, anti-A or anti-B agglutinins cannot attack the group O red cell

Before a diagnosis of erythroblastosis due to A-B-O incompatibility can be made properly, certain requisites must be fulfilled (1) The mother must be of blood group A, B or O (2) The infant must be of blood group A, B, or AB (3) There can be no incompatibility of the Rh factor, subgroups of the Rh factor, or the Hr factor between mother and infant, or if such incompatibility does exist, no antibodies to these factors can be present (4) There must be a titer of maternal anti-A or anti-B isoagglutinins of at least 1 500, since it is known that isoagglutinin titers of 1 500 or over can cause clinical evidence of agglutination and hemolysis in vivo [3]

In the course of our studies of the etiology of erythroblastosis, all newborn babies exhibiting jaundice are completely studied for evidence of blood incompatibility As a result of this, several cases of erythroblastosis were observed in which the requisites for A-B-O incompatibility were present Two of these are presented in detail

Case Reports

Case 1 —J K , a white, twenty-three-year-old primigravida, was delivered at term by low forceps of a 7 pound 7 ounce female infant after a twelve-hour labor The infant was apparently normal at birth, but twelve hours later jaundice was noted, accompanied by listlessness and lethargy The hemoglobin was 20 7 Gm and there were 1 per cent normoblasts present Icterus index was 71 During the next twenty-four hours the jaundice deepened, and the liver and spleen were palpably enlarged A diagnosis of erythroblastosis fetalis was made by Dr Philip Lombard, the pediatric consultant The blood groupings of mother and infant were as follows

Mother	Group O	Rh_1 Rh_2	Hr' positive
Infant	Group A	Rh_1 Rh_2	Hr' positive

The anti-A isoagglutinin titer of the mother's serum was 1 16 384

The anti-B isoagglutinin titer of the mother's serum was 1 8

A transfusion was given of 75 cc of Rh negative, Group O blood with an anti-A agglutinin titer of 1 25 and an anti-B titer of 1 4 (Rh negative blood was used because the blood workup was not complete at the time.) Immediately after the transfusion the jaundice increased, and the temperature rose to 101 F The next day there was marked improvement, the baby was more active, and the jaundice less pronounced Hemoglobin was 21 2 Gm Thereafter the infant continued to improve, the jaundice cleared, and the liver and spleen were not palpable The infant was discharged on the tenth day in good condition Hemoglobin was 20 0 Gm and the weight 7 pounds 4 ounces The subsequent course has been uneventful

Comment —This case meets the criteria for the diagnosis of erythroblastosis due to A-B-O incompatibility Since both mother and infant were of the same Rh phenotype, no Rh incompatibility could be present Furthermore, testing of both the mother's and infant's serums for Rh antibodies using O, Rh_1, and Rh_2 cells by both the agglutination and conglutination technics was negative The presence of other atypical antibodies was ruled out by testing both mother's and infant's serums against O, Rh positive and O, Rh negative cells with negative results No anti-A agglutinins could be demonstrated in the infant's serum This can be explained by assuming that these agglutinins were already bound up by the infant's A cells

Case 2 —T D , a white twenty-six-year-old gravida II, Para 1, was delivered at term by low forceps of an 8 pound 2 ounce male infant after a twenty-six hour labor The infant was apparently normal at birth and remained so until the second day when jaundice was noticed Examination disclosed the baby to be somewhat listless. The liver and spleen were both palpably enlarged Hemoglobin

was 21 2 Gm , and 1 per cent normoblasts were present A diagnosis of erythroblastosis fetalis was made by Dr Lombard A transfusion of 75 cc of group A, Rh negative blood was given (Rh negative blood was used because it was at first thought that this case was due to an intragroup Rh incompatibility) The infant responded well to the transfusion The icterus gradually faded, and the liver and spleen became normal in size The child was discharged on the twelfth day in good condition Hemoglobin was 23 9 Gm., and the weight was 7 pounds 14 ounces The baby has continued to thrive normally since The blood groupings of the mother and infant were as follows

Mother	O	MN	Rh_1	Hr′ positive
Infant	A_2	MN	Rh negative	Hr′ positive

The anti-A isoagglutinin titer of the maternal serum was 1 8,192

The anti-B isoagglutinin titer of the maternal serum was 1 8

Comment.—Case 2 also has the requisites for A-B-O incompatibility as the causative factor for erythroblastosis Since the baby was Rh negative, Rh antibodies could not have produced the erythroblastosis The presence of other atypical antibodies was again ruled out by testing both the mother's and infant's serums against O, Rh positive and O, Rh negative cells with negative results As in Case 1 no anti-A agglutinins could be demonstrated in the infant's serum.

Discussion

Although there have been several reports of erythroblastosis caused by A-B-O incompatibility between mother and infant, some investigators are somewhat loath to admit the existence of this syndrome [4] However, in the two cases reported, the diagnosis of erythroblastosis was established only after careful pediatric consultation and after every effort had been made to prove the absence of antibodies other than anti-A agglutinins

It is accepted that this disease is caused by the action of antibodies formed in the maternal blood which pass through the placental barrier into the fetal circulation and are incompatible with the fetal red cells It seems plausible to assert that there may be varying gradations of hemolysis and agglutination which can produce clinical symptoms of greater or lesser severity In our study of jaundice in the newborn, it is becoming more and more evident that so-called "physiologic icterus" is rarer than is supposed usually This may explain why the cases of erythroblastosis reportedly due to A-B-O incompatibility have been mild In addition, there is a natural immunity to anti-A and anti-B isoagglutinins, whereas there is no known immunity to Rh antibodies since they are not found naturally in human serum

It has been shown conclusively that a titer of anti-A or anti-B isoagglutinin of 1 500 or over can cause hemolysis if administered to an incompatible recipient [3] Hence, it appears logical that a higher titer of anti-A or anti-B maternal agglutinins can cause hemolysis of fetal red cells

The question of just what type of blood is to be transfused in the treatment of this syndrome is open to debate Apparently, blood compatible with the infant's blood group is effective, similarly group O blood with a low isoagglutinin titer appears to be safe and beneficial, as does group O blood modified with Witebsky's solution However, there are at least theoretic objections to the use of these bloods Since the isoagglutinin responsible for the erythroblastosis is incompatible with the infant's blood group, it can be argued that the addition of further blood of a similar group might be subject to the adverse action of the isoagglutinins Also, the addition of more isoagglutinins, even though of a very low titer, resulting from the use of group O blood might cause further hemolysis of the infant's blood The objection to the use of group O blood modified with Witebsky's solution is based on the fact that the added A and B substances are agglutinogenic in nature, are capable of antibody stimulation, and may conceivably result in subsequent difficulties Blood that contains neither agglutinogens nor isoagglutinins is ideal From these considerations it would seem that transfusion of washed group O, Rh compatible cells resuspended in normal saline is the most logical and safest means of therapy

While this syndrome is relatively uncommon, complete blood studies of jaundiced newborn babies would probably reveal many more cases Obstetricians should, therefore, be aware of the fact that erythroblastosis can occur in infants born of Rh positive mothers and hence should investigate all cases of jaundice occurring in the newborn Furthermore, the matter of A-B-O blood group incompatibility between mother and fetus should not be dismissed too lightly, as a recent statistical study gives rise to the provisional estimate that A-B-O isoimmunization is responsible for the loss of 3 per cent of all conceptions [5] This study also concludes that A-B-O isoimmunization acts early in fetal life to produce abortion, resulting in few cases of erythroblastosis fetalis

There has been a growing tendency against the use of pooled plasma This is principally because of the dangers of subsequent hepatitis Pooled plasma has been used in the past in order to reduce the isoagglutinin titer and so avoid hemolytic reactions The use of unpooled compatible plasma is certainly safe as it diminishes the risk of subsequent hepatitis, since in unpooled plasma only one donor is used (the new technic of

objecting pooled plasma to the action of the ultraviolet ray apparently destroys the virus responsible for hepatitis) and because the compatible plasma avoids all possibility of a hemolytic reaction. The syndrome of A-B-O incompatibility causing erythroblastosis is another argument against the use of pooled plasma, at least in females of the childbearing age. Such plasma, because it is made from various blood groups, contains both A and B substances which are antigenic and can cause an increase in the isoagglutinin titer. It has been shown that a high isoagglutinin titer is a requisite for erythroblastosis due to A-B-O incompatibility. Hence, the use of any substance likely to cause a rise in the isoagglutinin titer, such as pooled plasma or Witebsky's solution, should be avoided in females of the childbearing age.

Summary

The requisites for the diagnosis of erythroblastosis due to A-B-O incompatibility have been discussed. Two cases have been presented. The use of group O cells suspended in normal saline is advised in the treatment of this condition. A reference has been made to a statistical study which theorizes that A-B-O incompatibility plays a role in the etiology of abortion. Arguments for the use of compatible plasma in females of the childbearing age have been advanced.

LICENSURE OF FOREIGN MEDICAL GRADUATES

The statement issued by the Committee on Foreign Medical Credentials of the American Medical Association offers a statesman-like approach to the problems involved in the licensing of foreign-trained physicians.

The quality of education a physician receives during his medical school years is as important in determining his fitness to practice medicine as is his performance on licensure examinations. These, of necessity, are limited in the extent to which they can test his knowledge and skill. In licensing graduates of American and Canadian medical schools, the state licensing boards for many years have had the benefit of the findings of thorough periodic surveys of these schools carried out by the Council and the Association of American Medical Colleges. It has been beyond the resources of these bodies to make similar studies of the medical schools in other parts of the world. Other agencies have not been discovered which can furnish adequate information. Many state boards, therefore, have been reluctant to admit foreign-trained physicians to examinations. This reluctance has been justified, because medical education in many foreign countries has been inferior to medical education in this country. In many of the countries that previously maintained high standards, medical education has deteriorated during the past fifteen to twenty years as the result of political upheavals, the crushing impact of the war, and the unsettled economic and political conditions that have prevailed since the close of the war.

The Committee has drawn attention to these problems but has also recognized that in some foreign countries high standards of medical education comparable to those in the United States have been maintained. The Committee therefore has stated that the various agencies concerned with the problem should unite their resources and devise a satisfactory method for securing reliable information concerning foreign medical schools at the earliest possible date. When such information is obtained, it should be possible for the accrediting agencies to prepare a list of foreign medical schools whose graduates may be considered to have received training comparable to that offered by medical schools in this country. It would then seem reasonable that the state boards and the National Board of Medical Examiners admit graduates of these schools to examinations, provided they can demonstrate sufficient familiarity with recent scientific advances, with the practices and custom of American medicine, and with the English language. The Council on Medical Education and Hospitals will probably give major consideration to this suggestion at its next meeting.—*J. A. M. A., April 16, 1949.*

was 21 2 Gm , and 1 per cent normoblasts were present A diagnosis of erythroblastosis fetalis was made by Dr Lombard A transfusion of 75 cc of group A, Rh negative blood was given. (Rh negative blood was used because it was at first thought that this case was due to an intragroup Rh incompatibility) The infant responded well to the transfusion. The icterus gradually faded, and the liver and spleen became normal in size. The child was discharged on the twelfth day in good condition Hemoglobin was 23 9 Gm , and the weight was 7 pounds 14 ounces The baby has continued to thrive normally since The blood groupings of the mother and infant were as follows

Mother	O	MN	Rh_1	Hr' positive
Infant	A_2	MN	Rh negative	Hr' positive

The anti-A isoagglutinin titer of the maternal serum was 1 8,192

The anti-B isoagglutinin titer of the maternal serum was 1 8

Comment.—Case 2 also has the requisites for A-B-O incompatibility as the causative factor for erythroblastosis Since the baby was Rh negative, Rh antibodies could not have produced the erythroblastosis. The presence of other atypical antibodies was again ruled out by testing both the mother's and infant's serums against O, Rh positive and O, Rh negative cells with negative results As in Case 1 no anti-A agglutinins could be demonstrated in the infant's serum

Discussion

Although there have been several reports of erythroblastosis caused by A-B-O incompatibility between mother and infant, some investigators are somewhat loath to admit the existence of this syndrome [4] However, in the two cases reported, the diagnosis of erythroblastosis was established only after careful pediatric consultation and after every effort had been made to prove the absence of antibodies other than anti-A agglutinins

It is accepted that this disease is caused by the action of antibodies formed in the maternal blood which pass through the placental barrier into the fetal circulation and are incompatible with the fetal red cells It seems plausible to assert that there may be varying gradations of hemolysis and agglutination which can produce clinical symptoms of greater or lesser severity In our study of jaundice in the newborn, it is becoming more and more evident that so-called "physiologic icterus" is rarer than is supposed usually This may explain why the cases of erythroblastosis reportedly due to A-B-O incompatibility have been mild In addition, there is a natural immunity to anti-A and anti-B isoagglutinins, whereas there is no known immunity to Rh antibodies since they are not found naturally in human serum

It has been shown conclusively that a titer of anti-A or anti-B isoagglutinin of 1 500 or over can cause hemolysis if administered to an incompatible recipient [3] Hence, it appears logical that a higher titer of anti-A or anti-B maternal agglutinins can cause hemolysis of fetal red cells

The question of just what type of blood is to be transfused in the treatment of this syndrome is open to debate Apparently, blood compatible with the infant's blood group is effective, similarly group O blood with a low isoagglutinin titer appears to be safe and beneficial, as does group O blood modified with Witebsky's solution. However, there are at least theoretic objections to the use of these bloods Since the isoagglutinin responsible for the erythroblastosis is incompatible with the infant's blood group, it can be argued that the addition of further blood of a similar group might be subject to the adverse action of the isoagglutinins Also, the addition of more isoagglutinins, even though of a very low titer, resulting from the use of group O blood might cause further hemolysis of the infant's blood The objection to the use of group O blood modified with Witebsky's solution is based on the fact that the added A and B substances are agglutinogenic in nature, are capable of antibody stimulation, and may conceivably result in subsequent difficulties Blood that contains neither agglutinogens nor isoagglutinins is ideal From these considerations it would seem that transfusion of washed group O, Rh compatible cells resuspended in normal saline is the most logical and safest means of therapy

While this syndrome is relatively uncommon, complete blood studies of jaundiced newborn babies would probably reveal many more cases Obstetricians should, therefore, be aware of the fact that erythroblastosis can occur in infants born of Rh positive mothers and hence should investigate all cases of jaundice occurring in the newborn Furthermore, the matter of A-B-O blood group incompatibility between mother and fetus should not be dismissed too lightly, as a recent statistical study gives rise to the provisional estimate that A-B-O isoimmunization is responsible for the loss of 3 per cent of all conceptions [5] This study also concludes that A-B-O isoimmunization acts early in fetal life to produce abortion, resulting in few cases of erythroblastosis fetalis

SEGMENTAL COLITIS ASSOCIATED WITH RHEUMATIC FEVER

BARNET M HERSHFIELD, M D , and DAVID N MARKS, M D , New York City

(From the Departments of Medicine and Surgery, Jewish Memorial Hospital)

THE purpose of this paper is to call attention to the coexistence of a regional inflammatory lesion of the large bowel with active rheumatic infection This phenomenon was observed in two cases in which the picture of a surgical abdomen was simulated and explorations were performed Except for the anatomic location of the lesion in the colon, the findings were identical

There are numerous reports of abdominal complaints associated with latent rheumatic fever in which surgical syndromes are mimicked The findings of those who have examined some of these cases at laparotomy revealed only peritoneal fluid ranging from a clear or straw-colored transudate to an exudate that may be fibrinous, hemorrhagic, or purulent [1] No other gross pathology was visualized, and there was no suggestion of rheumatic inflammation in any of the vermiform appendices which were removed [2]

There is no satisfactory explanation of the mechanism of the abdominal symptoms in rheumatic fever The attack with abdominal signs and symptoms usually appears when the patient is enjoying a quiescent phase After the subsidence of the abdominal symptoms with or without surgery, the more typical manifestations of arthritis and carditis may appear to suggest the nature of the recent abdominal picture In a few of the reported cases, a waning acute attack can be complicated by the onset of abdominal pain, nausea, and vomiting

Actual pathologic studies of this condition are rare Rhea, in a large number of postmortem examinations of cases of rheumatic fever at the Montreal General Hospital, found only one case with rheumatic lesions of the peritoneum [3] In this case, the peritoneal cavity contained approximately 500 cc of clear, straw-colored fluid Plaquelike areas were palpable in the subperitoneal tissues laterally and posteriorly The peritoneum in these areas showed the general features of inflammation, it was dull, hyperemic, and granules of fibrin were adherent The walls of the mesentery and the intestines were edematous and congested Microscopically, the peritoneal lesions were similar to those in the heart, i e, "congestion of the blood vessels and irregularly distributed monocytes"

Pappenheimer and Von Glahn, in studying cases of rheumatic fever, found that the rheumatic lesions in many tissues were vascular and consisted of phlebitis and periarteriolitis [4] The vascular changes were found in the following sites lung, aortic valve, kidney, perirenal and periadrenal adipose tissue, appendices epiplocae of the sigmoid colon, ovary, testes, pancreas, and in a small polyp of the cecum Felsen described a case with intrinsic pathology in the bowel wall in a woman who died with accompanying rheumatic and arthritic lesions The terminal ileum and ascending colon of this patient contained focal ulcerative and necrotic lesions "The histologic study of these lesions demonstrated a resemblance to the specific rheumatic lesions about the peripheral blood vessels in many organs described by Von Glahn and Pappenheimer"[5]

In the two cases which are the subject of this report, discrete segments of the colon were found to be markedly injected, thickened, and brawny, while the remainder of the gastrointestinal tract was normal in appearance In one case, the lesion involved the cecum and first portion of the ascending colon, while in the second the terminal portion of the sigmoid and the rectosigmoid were affected

Case Reports

Case 1—J H , a married Chinese woman, aged twenty-four years, was admitted to the Jewish Memorial Hospital on January 1, 1942, with a history of acute follicular tonsillitis three weeks prior to admission This condition subsided within a few days Ten days before admission, the patient had an onset of low-grade temperature accompanied by a short, hacking cough and aching pains in the lumbar region For the two days prior to admission, there was constant nausea and postprandial vomiting In the past history, the only pertinent fact was an attack of acute rheumatic fever one year previously

The admission temperature was 103 F , pulse 128 and respiration 22 The positive findings on examination were a mild inflammation of the pharynx and a short systolic murmur, best heard just to the left of the sternum. There was no tenderness or spasm of the abdomen or flanks The laboratory data showed the urine to contain a slight trace of albumin and a 4 plus acetone The red blood cells were 3,790,000, hemoglobin 10 Gm., white blood cells 31,850 with a differential of polymorphonuclears 65 per cent, stabs 23 per cent, lymphocytes 6 per cent, and monocytes 5 per cent A markedly elevated sedimentation rate of 102 mm per hour (Westergren) was recorded Admission blood culture and agglutination tests, i e typhoid O and H, paratyphoid A and B, melitensis, and Felix Weil, all proved negative Roentgen study of the chest revealed no pulmonary pathology On the basis of

these findings, the diagnoses made in order of preference were (1) acute rheumatic fever (2) possible subacute bacterial endocarditis, and (3) enteric fever to be ruled out

The patient was observed closely during the following five days for a specific focus to explain a continued high temperature elevated sedimentation rate, and leukocytosis The frequent vomiting which had caused an acidosis was not evident in the hospital. There were no subjective complaints during this period, but on January 23 the presence of tenderness in the right flank was detected Within twenty-four hours this area became excruciatingly tender and the musculature spastic, yet the patient did not complain of pain in this region Repeated blood studies revealed a decrease in leukocytosis to 23,700 but with a marked shift to the left with 34 per cent stabs and 41 per cent segmented polymorphonuclear cells With this changing picture, the attending physician made the provisional diagnosis of pernephritic abscess. Dr Edward Blair, in consultation, felt that an exploration was justified

The abdomen was opened under general anesthesia on the fifth day of the patient's hospital admission The cecum and lower portion of the ascending colon were found markedly thickened and red with considerable edema of the serosa The appendix was found curled up under the cecum in similar condition but was apparently not the primary cause The ileum was normal No clinical diagnosis could be made as to the nature of the condition The appendix was removed and the wound closed after 5 Gm. of sulfathiazole powder were placed in the peritoneal cavity

The patient's postoperative course was complicated on the fourth day by the onset of pain in the right knee and shoulder and, associated with this was the swelling of the right knee and a secondary rise in temperature The arthritic symptoms subsided in a few days Further evidence of rheumatic activity during the postoperative period was a markedly elevated sedimentation rate of 114 mm in one hour, an electrocardiogram which showed a first stage heart block with a P-R interval of 0 22 second, and the clinical observation of a systolic murmur to the left of the sternum in the second intercostal space Otherwise the postoperative period was characterized by a gradual lysis of fever which had varied between 101 and 104 F during the first week to normal during the second week. The patient was discharged to return home by ambulance for further convalescence on the fourteenth postoperative day

Case 2 —A. S , a young white man, aged seventeen years, was admitted to the Jewish Memorial Hospital on June 2, 1947 A history was obtained of typical recurrent attacks of rheumatic fever over a ten-year period His present illness began five weeks prior to admission with a low-grade fever and signs of a mild upper respiratory infection. The patient was confined to bed in his home and during the following weeks he continued to run an intermittent temperature and had migratory joint pains Two days prior to admission, there was an onset of low-grade suprapubic pain which in twenty-four hours localized to the right lower quadrant The patient's appetite was poor and there was some nausea and vomiting, bowel movements were regular The patient was then hospitalized for closer clinical observation and laboratory studies

On admission, the temperature was 104 F pulse 120 and respiration 22 Examination revealed a freely perspiring sickly adolescent male with pallid, drawn facies The tongue was furred and brown A heaving apical beat was observed below and to the left of the left nipple, and a systolic thrill was palpable in this area A systolic murmur was heard over the apex and it was transmitted toward the left axilla, no diastolic murmurs were heard Moderate tenderness was found across the suprapubic area but no rebound or muscle spasm. Rectal examination revealed slight tenderness in both lower quadrants. Extremities were negative The admission diagnoses were (1) acute rheumatic fever, (2) subacute bacterial endocarditis, and (3) abdominal adenitis with peritoneal irritation

Laboratory data on admission included a sedimentation rate of 70 mm in one hour, red blood cell count of 3,800,000, hemoglobin 12 5 Gm , white blood cells 20,000 and a differential revealing polymorphonuclears 76 per cent, nonsegmented polymorphonuclears 9 per cent, lymphocytes 14 per cent, and monocytes 1 per cent The urine was negative except for many white blood cells without clumping In numerous re-examinations of urine specimens this finding recurred but once, and its significance was never appraised X-ray of the chest was negative for pulmonary pathology

During the first thirty-six hours in the hospital, the mild suprapubic symptoms and signs shifted and localized to the right lower quadrant The patient complained of persistent pain in that area, but there was no nausea or vomiting At this stage, the patient was seen in consultation by the authors, and examination disclosed exquisite tenderness over an entire area that was within a radius of 3 inches of McBurney's point There was moderate voluntary muscle spasm and a vague sense of mass in this region, rebound tenderness was not present During this period in which there was localization of signs to McBurney's point, there was an increase in leukocytosis to 31,000 with no appreciable change in the differential white cell count

The clinical impression at this time was that the abdominal signs and symptoms could be a manifestation of rheumatic fever but that acute appendicitis with abscess formation and a walling-off process could not be ruled out It was decided to watch the patient carefully, maintaining him on a modified Ochsner regime, and to administer penicillin 100,000 units, every three hours In another twenty-four hours, the patient complained of spread of pain to the left lower quadrant Examination disclosed the same findings on the right side with extension of signs across the midline to the left lower quadrant Tenderness and voluntary muscle spasm in this new area were quite pronounced but, as on the right side there was no rebound tenderness

It was felt that in view of the signs of persistent and spreading peritoneal irritation, expectant treatment could not be pursued without great danger if

the pathology was appendiceal. Exploratory laparotomy was performed under spinal anesthesia on the third day of the patient's hospitalization. Prior to incision which was to be a McBurney, the abdomen was palpated, and instead of feeling the expected mass in the right lower quadrant, one was distinctly palpated in the left lower quadrant. The incision was changed to a paramedian and upon opening the peritoneal cavity, a small amount of clear amber fluid was found. Inspection revealed a mass in the left lower quadrant which was composed of a matting together of collapsed small bowel and a markedly edematous, injected sigmoid and rectosigmoid. The serosa of the involved colon was deeply hyperemic, and the bowel wall itself was thick and pipe-stemmed. The epiplocae in this area was spotted with many injected vessels. A few small fibrinous patches were present on an otherwise normal small intestine. The serosa of the cecum was slightly hyperemic, but that portion of the colon was essentially normal in appearance. After culturing and suctioning off the peritoneal fluid, the plastic adhesions were easily separated, the organs inspected, and then an appendectomy performed.

Postoperatively, there was gradual improvement on oral salicylate therapy and within a week a complete disappearance of the abdominal signs and symptoms. The patient continued to run a recurrent temperature for five weeks before it leveled off and stayed within normal limits. Throughout this period, a constant tachycardia around 120 was maintained, and the sedimentation rate on successive weeks was 70, 84, 85, 35, and 33 mm. per hour. The antifibrinolytic titer on June 28 was 4 plus. Electrocardiograms taken on June 16 and 27 showed a left axis deviation, upright T waves in all leads, and a slurred QRS in the third, the P-R interval was not prolonged. Cultures of blood and peritoneal exudate were negative for growth.

The patient was discharged from the hospital after forty-one days. For a short period he was well, and then there was a recrudescence of rheumatic fever in severe form characterized by pancarditis and myocardial insufficiency.

Pathology

The microscopic findings and comments by Dr. Alfred Angrist are presented in detail. They support our impression that the gastrointestinal lesions may well represent exudative rheumatic manifestations.

Case 1.—Tissue: Appendix (microscopic).—The serous coat shows an outstanding edema, so that the serosa is thrown up in folds. Some of the included lymphatics are engorged with serous lymph material and distended by same. The interstices of the stroma are filled with similarly staining edema fluid. Throughout the serous coat and oriented to the surface in some areas are seen foci of palisaded, proliferating histiocytes. These are prominent in some of the serosal folds, as noted, and an occasional focus shows minute necrosis. A fibrinous exudate forms a thin adherent membrane on the surface of the peritoneum in some areas. Some of the histiocytes can be seen invading this surface zone of exudate. The exudate about some of the venules is quite marked, with round cells present in considerable numbers and some prominent histiocytes with a parallel arrangement. Some of the histiocytes are quite large and show large nuclei and parallel orientation, but no multinucleated giant cells can be made out. One small venule shows a subendothelial proliferation of such cells, giving origin to a hillock, verrucous-like protrusion into the lumen. The remainder of this vessel shows polynuclear exudation beneath the intima and regional edema.

The remaining coats show engorgement of the vessels with some perivascular round-cell infiltration extending into the muscular coat. The mucosa and submucosa show no remarkable changes.

FIG. 1. Edema and inflammatory infiltration in serosa of appendix. Note fibrin deposit.

Case 2.—Tissue: Appendix and sigmoidal appendix epiploica (microscopic).—Section of the appendix shows considerable edema of serous coat with considerable round-cell infiltration (Figs. 1 and 2). A thin layer of fibrinoid material is found on the serous surface. Inflammatory round cells are noted about numerous vessels of the serous coat, but polynuclear elements are found attached to the endothelium and extending into the lumen and in the wall proper of some of the small venules. Some proliferating fibroblasts are seen. Large histiocytes are not prominent in this section. Some of the fibrinoid material shows beginning organization. Some of the venules show evidence of endo- and periphlebitis.

Some perivascular infiltration is noted extending into the muscle coat, with the muscle coat showing round cells about some of the smaller vessels.

The appendix epiploica shows a prominent thin surface layer of fibrinoid material with adjacent inflammatory exudation. Some of the fibrinoid material is present in globule form, most of it, however, appearing as a laminated layering. The adja-

cent tissue shows prominent exudation with some nonstaining edema fluid in the fat and again considerable perivascular round-cell infiltration Some histiocytes are present in the stroma about some of the venules and very small arterioles Fibrinoid material can be seen extending into the fat of the appendix epiploica, corresponding to the thin septal trabeculae

Comment.—Both of the above cases show an indolent inflammatory reaction in the stroma of the serous peritoneal coat with a fibrinoid surface exudation. The inflammatory reaction is of a diffuse character, although mild, and shows a distinct orientation to the vasculature, as noted Although no specific histologic manifestation of a rheumatic infection is found, the above reaction has been seen in the synovial membranes of joints of known cases of rheumatic fever

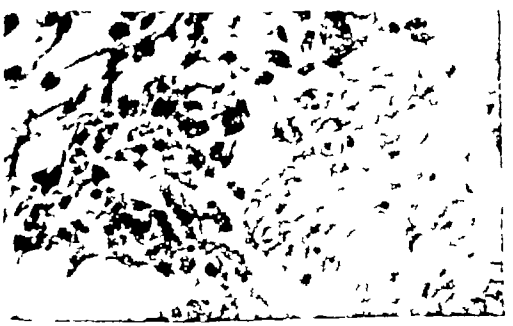

FIG 2 High power magnification of the serosa of the appendix showing perivascular inflammatory infiltration

Differential Diagnosis

The freedom from symptoms, such as diarrhea, straining, urgency, and mucoid or bloody stools, and the noteworthy lack of chronicity are important points in differentiating these cases from other intestinal syndromes, such as malignancy, specific colitis such as tuberculosis and syphilis, regional ileitis, and nonspecific colitis, which may be universal or segmental Of greatest interest in the differential diagnosis is the latter condition, also known as right-sided colitis

Crohn, Garlock, and Yarnis, in reviewing a series of 77 cases of this syndrome, mentioned that in one case acute endocarditis with a blowing systolic murmur and fever developed while the patient was under observation [6] In two cases, they found pre-existent rheumatic valvular disease which was accepted as being purely coincidental They hypothecate a specific type of chronic valvular disease of the heart arising solely as a complication of segmental colitis and not related to any previous rheumatic infection

The sequence of events and findings in our patients is different The distinguishing features in the two cases presented are as follows (1) The primary disease was acute rheumatic fever, (2) the abdominal lesions occurred during the active stage of the disease, and (3) the brief duration, a spontaneous recession, the absence of stool abnormalities, a high leukocyte count, and the absence of pronounced mesenteric lymphadenopathy were noteworthy

The two instances presented above give no evidence of avitaminosis in which condition segmental bowel changes have been described

Discussion

No pathologic studies were made of the gross lesions in the colon as biopsy was not feasible However, it is felt that in the first case the vermiform appendix, being an involved contiguous structure, probably reflected the picture in the colon In the second case, the appendix, while not grossly involved in the process, did show similar changes, suggesting the possibility of widespread involvement of the intestinal tract

The lesions of the colon observed in the foregoing cases may represent a local manifestation of the exudative phenomenon of rheumatic activity While not accepted by all authorities on rheumatic fever, it is likely that this type of reaction is allergic or anaphylactoid in character That the gastrointestinal tract may act as a shock organ was first demonstrated experimentally by Gray, Harten, and Walzer [7] They induced an allergic reaction in the passively sensitized mucous membranes of the rectum, ileum, and colon by the oral administration of a specific antigen

Rich and Gregory, while making no claim to having finally settled the question of the pathogenesis of rheumatic fever, have experimentally reproduced the disease picture as it so commonly occurs in man by hypersensitivity of the anaphylactic type [8] They also point out that most students of the pathology of rheumatic lesions are agreed that a fundamentally important manifestation of the condition is focal injury to the connective tissue characterized by edema with swelling and degeneration of collagen fibrils, as well as the frequent occurrence of inflammatory, necrotic arterial lesions (the so-called rheumatic arteritis)

The absence of Aschoff bodies in tissue specimens from our patients again emphasizes the fact that these structures are but rarely demonstrated outside of the myocardium [9] Of particular interest is Dr Angrist's comment on the similarity between the lesions in these cases and those in the synovial membrane of joints in known cases of rheumatic fever

Summary

There are presented in this article two cases of acute rheumatic fever, which, upon exploration for surgical abdominal syndromes, revealed acute segmental lesions of the colon that resolved spontaneously within a week.

In Case 1, the abdominal signs were preceded by an attack of tonsillitis and were followed within a few days by polyarthritis In Case 2, the clinical picture of active rheumatic fever preceded the onset of colonic involvement

Inasmuch as the colonic lesions do not correspond with any known pathologic condition of the large bowel, and because of the suggestive evidence presented, it is felt that they may represent an exudative colonic manifestation of rheumatic infection

STATISTICS REFUTE EWING'S CLAIM FOR REDUCTION OF DEATHS

Refuting Federal Security Administrator Oscar Ewing's claim that 325,000 of the 1,400,000 deaths which occur annually in the United States are preventable, an editorial in the May 28 issue of the *Journal of the American Medical Association* said that no health program, system of health insurance, or amount of medical progress could make this reduction

Such a decrease would bring the annual number of deaths below the number in any year since 1900 when the population of the United States was only half what it is today Moreover, the editorial indicated, use of the annual number of deaths as a measure of health progress is fallacious

Health progress and the number of deaths each successive year are simply two different ideas, the editorial pointed out

Obviously this reduction cannot be accomplished in an increasing and aging population because the total number dying each year in any nation depends on the number of people, their ages, and the death rate per thousand at each age. Nor can the annual number of deaths be kept from actually increasing during the coming years

Twenty years ago the number of deaths was 100,000 less than last year, and life expectancy at birth was seven years less. Twenty years from now the number of deaths in our aging population may well be 1,500,000 to 1,600,000, the length of life doubtlessly will be greater, and the mortality rate for each age will be lower than now

The task of the medical profession over the years is to raise the average age at death, reduce the importance of the "younger" causes of death, and increase the importance of the "older" causes of death.

Among the many unsupported claims made by the Federal Security Administrator in his promotion of a compulsory health insurance program is the reduction of the number of accidental deaths annually from 100,000 to 60,000, or by 40 per cent

However, physicians realize that a comprehensive scheme for an extensive reorganization of the nation's medical services could not possibly eliminate 40 per cent of accident fatalities. If the accidental death reports published yearly by the Kansas State Board of Health are to be taken as representative of the country as a whole, the proposal is untenable For 1945, 1946, and 1947, a total of 4,103 fatal accidents occurred in Kansas. Of these, 1,930 deaths, or 47 per cent, occurred instantaneously and 2,468 deaths, or 60 per cent, occurred instantaneously or within one day after the fatal accident. The remaining 40 per cent died after 24 hours.

By a strange coincidence, the administrator believes that he can save 40 per cent of lives lost in all fatal accidents. According to the Kansas statistics—the best in the United States on this point—the administrator apparently proposes to guarantee survival to all who remain alive for 24 hours after an accident—or to an equivalent number The physicians would like to know how compulsory health insurance would save those lives.

THE SURGICAL TREATMENT OF HEART DISEASE

CLINICAL ASPECTS OF CONGENITAL CARDIAC LESIONS AMENABLE TO SURGICAL THERAPY

JANET S BALDWIN, M D , New York City

(From the Children's Medical Service, Bellevue Hospital and the Department of Pediatrics, New York University College of Medicine)

THE need for accurate clinical diagnosis in congenital anomalies of the heart and great vessels has been accentuated by the development of surgical procedures that now make possible the cure or alleviation of a group of these anomalies As these operative procedures are best carried out during the childhood years, the responsibility for initial recognition of those conditions which can be helped falls largely upon the pediatrician or general practitioner caring for this age group

Clinical Methods of Study

Establishment of the diagnosis is possible in the majority of cases of congenital heart disease by readily available clinical methods [1] These include close attention to details of the physical examination of the cardiovascular system, fluoroscopic and x-ray studies, and analysis of the electrocardiographic record

The presence or absence of clubbing and cyanosis are of immediate diagnostic aid Occasionally cyanosis becomes definite only after exercise Unless contraindicated by the presence of dyspnea or considerable cyanosis at rest, the heart should be examined and blood pressure taken before and immediately after exercise Palpation of the femoral arteries should be carried out routinely In analyzing congenital cardiac anomalies it is essential that palpation and auscultation be carried out over the entire precordium. Careful evaluation should be made of the exact location of thrills, abnormal accentuation or decrease in intensity of the heart sounds, and site of maximum intensity, direction of transmission, and quality of murmurs

With eyes well accommodated, a thoughtful fluoroscopic examination of the contour of the heart and great vessels in the anteroposterior and both oblique views is invaluable. The type of pulsations at various points can be observed directly It is particularly important to note increase or decrease in amplitude of pulsations of the pulmonary artery and vascular markings in the hilar areas The course of the barium-filled esophagus should be studied for abnormal displacement or compression In addition, x-rays are valuable for basic record measurement of cardiac size, and clearer visualization of the pulmonary vascular markings

Determination of circulation time from arm to lips or tongue may be helpful in certain cases Shortening of this time below the normal value for the age of the given case indicates the presence of a venous-arterial shunt Because of the sharp objective end point obtained, the use of fluorescein is preferable to decholin in younger children and infants

Evaluation of the axis deviation of the electrocardiogram gives information as to the proportionate mass of the two ventricles present in individual cases

In many cases of congenital heart disease diagnosis is possible from the synthesis of information gathered from these standard clinical methods of study However, for complete establishment of the diagnosis in certain instances, recourse may be necessary to procedures such as angiocardiography and venous catheterization of the heart [2,3] These procedures entail special equipment and a well-trained team of investigators which, of necessity, are available at present only in larger centers of investigation.

Conditions Amenable to Surgical Therapy

To date, surgical procedures are available for the following conditions patent ductus arteriosus, coarctation of the aorta, anomalies of the aortic arch causing pressure, and the tetralogy of Fallot Surgical investigations are in progress as to relief in valvular pulmonary stenosis, closure of septal defects, and measures to improve the circulation in transposition of the great

Presented at the 143rd Annual Meeting of the Medical Society of the State of New York, Buffalo General Sessions May 6 1949

STATISTICS REFUTE EWING'S CLAIM FOR REDUCTION OF DEATHS

Refuting Federal Security Administrator Oscar Ewing's claim that 325,000 of the 1,400,000 deaths which occur annually in the United States are preventable, an editorial in the May 28 issue of the *Journal of the American Medical Association* said that no health program, system of health insurance, or amount of medical progress could make this reduction

Such a decrease would bring the annual number of deaths below the number in any year since 1900 when the population of the United States was only half what it is today Moreover, the editorial indicated, use of the annual number of deaths as a measure of health progress is fallacious.

Health progress and the number of deaths each successive year are simply two different ideas, the editorial pointed out

Obviously this reduction cannot be accomplished in an increasing and aging population because the total number dying each year in any nation depends on the number of people, their ages, and the death rate per thousand at each age. Nor can the annual number of deaths be kept from actually increasing during the coming years

Twenty years ago the number of deaths was 100,000 less than last year, and life expectancy at birth was seven years less. Twenty years from now the number of deaths in our aging population may well be 1,500,000 to 1,600,000, the length of life doubtlessly will be greater, and the mortality rate for each age will be lower than now

The task of the medical profession over the years is to raise the average age at death, reduce the importance of the "younger" causes of death, and increase the importance of the "older" causes of death.

Among the many unsupported claims made by the Federal Security Administrator in his promotion of a compulsory health insurance program is the reduction of the number of accidental deaths annually from 100,000 to 60,000, or by 40 per cent

However, physicians realize that a comprehensive scheme for an extensive reorganization of the nation's medical services could not possibly eliminate 40 per cent of accident fatalities. If the accidental death reports published yearly by the Kansas State Board of Health are to be taken as representative of the country as a whole, the proposal is untenable For 1945, 1946, and 1947, a total of 4,103 fatal accidents occurred in Kansas Of these, 1,930 deaths, or 47 per cent, occurred instantaneously and 2,468 deaths, or 60 per cent, occurred instantaneously or within one day after the fatal accident. The remaining 40 per cent died after 24 hours.

By a strange coincidence, the administrator believes that he can save 40 per cent of lives lost in all fatal accidents. According to the Kansas statistics—the best in the United States on this point—the administrator apparently proposes to guarantee survival to all who remain alive for 24 hours after an accident—or to an equivalent number The physicians would like to know how compulsory health insurance would save those lives.

traindicate but rather enhances the need for surgical intervention to eliminate the added strain from the shunt through the patent ductus arteriosus

When cyanosis is noted or there is considerable right axis deviation in the electrocardiogram in the presence of murmurs of a patent ductus arteriosus, careful investigation is imperative to determine the presence of an associated pulmonary stenosis prior to consideration of surgery In this circumstance the patency of the ductus arteriosus serves a physiologic compensatory function in maintaining sufficient flow of blood to the lungs Hence, elimination of this shunt under such circumstances is contraindicated

Coarctation of the Aorta—Coarctation of the aorta is a constriction of this vessel at the distal end of the arch, usually just beyond the level of the origin of the left subclavian artery This condition may be associated with severe cardiac abnormalities which are incompatible with life beyond a short span In other cases it may occur alone or associated with less significant cardiac abnormality and is compatible with life into the adult years [5]

The outstanding effects of coarctation of the aorta are increased blood pressure above the constriction with low pressure in vessels below this area and the development of collateral circulation To circumvent the narrowing in the aorta, the greater part of the blood flow to the lower portion of the body must pass through collateral arterial pathways The collateral circulation occurs from branches of the subclavian arteries (1) through branches of subscapular and intercostal arteries to the descending aorta and (2) through the internal mammary, superior and inferior epigastric arteries to the iliac arteries The development of the collateral circulation becomes more marked with growth Due to the increased flow and pressure in these arteries they become abnormally tortuous, dilated, and prominent Pulsation of these vessels may be visible under the skin of the chest and abdomen The continuous pulsations in the posterior intercostal arteries lead to erosions of the lower margins of the ribs

Symptoms are quite frequently lacking, especially in the younger group When present they include headache, dizziness, epistaxes, and complaints of weakness and coldness of the legs Physical development is usually not impaired, and there is no evidence of clubbing or cyanosis The outstanding finding is hypertension in the arms and absent or feeble pulsations of the femoral artery with low or unobtainable blood pressure in the legs Normally, systolic pressure in the lower extremities is higher than that in the arms, and the finding of reversal of this relationship is of immediate diagnostic significance The pressures, both systolic and diastolic, in the arm range from only moderately above normal values in some cases to very high readings in others

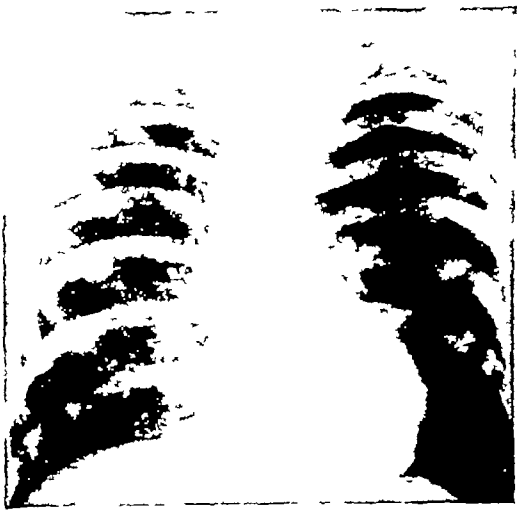

FIG 1 Coarctation of the aorta—posteroanterior view

A systolic murmur over the base of the heart may be present, but frequently the only abnormality noted on auscultation is accentuation of the second aortic sound On fluoroscopy and x-ray the heart is usually relatively normal in size or shows slight left ventricular hypertrophy, and the aortic knob may be small (Figs 1 and 2)

FIG 2 Coarctation of the aorta—left anterior oblique view

vessels These latter procedures, however, have not been sufficiently studied or enough cases operated upon to warrant their discussion in this presentation

Patent Ductus Arteriosus—The ductus arteriosus serves an essential purpose during fetal life The lungs being unexpanded, most of the blood entering the pulmonary artery is shunted directly through the ductus into the aorta With the onset of respiratory function after birth, the blood pumped from the right side of the heart is directed into the pulmonary vascular bed for oxygenation, and the ductus arteriosus is, therefore, no longer needed The lumen of this vessel gradually becomes obliterated under normal circumstances, this process usually being completed by the end of the second month

Patency of the ductus arteriosus may persist in certain individuals, due to as yet poorly understood causes In postnatal life, because the pressure in the systemic circulation is higher than that in the pulmonary circulation, the flow of blood is from the aorta into the pulmonary artery The anatomic and physiologic effect of this arteriovenous fistula may be great or slight, depending upon the size of the ductus and the amount of blood shunted Both sides of the heart are affected by this condition The pulmonary vascular flow is increased by the added volume entering from the aorta, which causes *an extra load to be driven forward by the right* ventricle The increase in volume flow returning from the lungs in turn increases the size, output, and work of the left side of the heart Due to the persistent increased blood flow through the lungs, pulmonary hypertension may occur

Clinically definite symptoms can be almost lacking where the flow through the ductus is small, but with a large flow and considerable cardiac enlargement the symptoms may be quite prominent In the latter instance, there may be history of repeated pulmonary infection Fatigability and exertional dyspnea are apt to be present The individual may present a certain degree of underdevelopment and pallor No clubbing is present In the absence of congestive failure or pulmonary disease, there is no cyanosis

On cardiac examination the classic finding is the continuous murmur in systole and diastole which is heard with maximum intensity at the second interspace to the left of the sternum and is often rather widely transmitted over the precordium[4] The murmur has a characteristic rasping or *roaring quality* and is variously described as resembling "a train in tunnel," "the continuous running of a machine," or "rolling thunder" A thrill corresponding in time and location to the murmur is frequently palpable Both murmur and thrill are frequently maximal in the recumbent position Due to the increased pressure in the pulmonary circuit, considerable accentuation of the second pulmonic sound is usually noted Where a large shunt of blood is present, the systemic blood pressure will show a wide pulse pressure *and further lowering of the* diastolic level after exercise

It should be noted that in infants and young chirlden the diastolic component of the murmur may not be audible This is explained by the relatively low systemic blood pressure in this age group, and, although some blood probably is passing through the ductus during diastole, the rapidity and volume is not sufficient to create an audible murmur

Fluoroscopic and x-ray findings vary considerably from case to case Prominence of the pulmonary conus and expansile pulsations of the pulmonary artery and hilar vessels are present in many cases but are less notable or absent in others The size of the heart ranges from nearly normal to a moderate degree of enlargement of both ventricles, usually dependent on the amount of flow through the ductus With large flow evidence of pulmonary engorgement and enlargement of the left auricle may also be found

The electrocardiogram in the majority of instances shows no axis deviation due to the fact that both ventricles share the effect of this shunt *Significant right axis deviation should promptly* raise the question of an associated pulmonary stenosis

In the presence of a classical murmur the diagnosis of a patent ductus arteriosus presents no problem The establishment of a definite diagnosis may be difficult in the early age group before the diastolic murmur is clearly heard, as previously mentioned Other conditions which can create a loud systolic murmur in the same area are pulmonary stenosis, a high interventricular defect, or an interauricular defect Occasionally, in the latter conditions associated with large blood shunts, if there is sufficient enlargement of the pulmonary artery, pulmonary regurgitation may be present, and a diastolic murmur may also be heard This diastolic murmur of regurgitation is, however, almost always softer, more blowing in quality, and is usually better heard further down the left sternal border than the rough diastolic component present with a patent ductus arteriosus

Usually a patent ductus arteriosus occurs as an isolated anomaly, but occasionally it may be associated with an interventricular septal defect, or there may be superimposed rheumatic heart disease The presence of this particular congenital anomaly or acquired mitral disease, provided the rheumatic process is inactive, does not con-

in the anterior view (Fig 3) Where a right aortic arch crosses behind the esophagus to descend on the left, there is a transverse posterior compression of the barium-filled column at the level of the third or fourth vertebra (Fig 4) The course of an anomalous subclavian artery is seen as a compression which runs obliquely across the upper part of the barium-filled esophagus.

When these anomalies cause serious symptoms, which are most prone to occur in infants, surgical intervention is indicated Release of the "ring and relief of pressure is accomplished by division of one of the vascular structures displacing the right aortic arch or the lesser of the two sides of a double aortic arch. An anomalous right subclavian artery can be ligated and divided Gross has reported good results in several cases of the above types [6]

Tetralogy of Fallot and Other Cardiac Anomalies Causing Cyanosis—There is a variety of congenital cardiac abnormalities which cause persistent cyanosis Many of these cases do not survive beyond the first weeks or months of life Of those who survive longer, it is estimated that about 75 per cent are instances of the tetralogy of Fallot The four features of this syndrome consist of pulmonary stenosis, dextraposition of the aorta which thus overrides and receives blood from both ventricles, a high interventricular septal defect, and hypertrophy of the right ventricle The stenosis is most frequently located at the infundibular area of the right ventricle The results of these malformations are a decrease in volume of blood reaching the lungs for oxygenation and an admixture of arterial and venous blood pumped into the aorta Arterial oxygen saturation is thus lowered In an attempt to compensate for this hypoxia there is development of polycythemia

Fig 5 Tetralogy of Fallot—posteroanterior view

Fig 6 Tetralogy of Fallot—left anterior oblique view

Cyanosis may not be noted during the first months of life when the ductus arteriosus frequently remains open to supplement the flow of blood to the lungs As this vessel tends to become obliterated and with progressive growth and activity of the infant, the degree of hypoxia increases, and cyanosis becomes apparent Clubbing of the fingers and toes develops gradually, depending on the degree of oxygen deficiency present in individual cases Symptoms due to hypoxia include dyspnea, often paroxysmal in type and accompanied at times with episodes of unconsciousness during which there may be twitching or frank convulsions These cases show a typical response when fatigued if erect, they will squat on their heels, the same reaction appearing in the infant who is seen to draw up his knees toward the chest and usually prefers to lie on his abdomen in this position [7]

Examination of the heart usually reveals no significant enlargement The second pulmonic sound is clear and often decreased in intensity Location and intensity of systolic murmurs are variable, being in some cases quite loud over the pulmonic area transmitting upward to the clavicle, in others best heard over the lower precordium, and in some instances, especially in infants, no definite murmur is audible There is no diastolic murmur Fluoroscopic and x-ray examination is much more helpful in establishing the diagnosis than auscultation (Figs 5 and 6) The characteristic features are a heart relatively

FIG 3 Right aortic arch Impingement on right side of barium-filled esophagus, as seen in posteroanterior view

In some cases there is prominence of the ascending aorta Notching of the inferior border of ribs is a strongly suggestive finding which, however, is only rarely clearly visualized before the age of ten to fourteen years In the left anterior oblique view the ascending aorta appears to rise unusually high toward the apex of the chest due to the increased size of the vessels arising from the arch The electrocardiogram frequently shows some left axis deviation

The differential diagnosis is rarely a problem, as cases of hypertension due to other causes will not show the difference in blood pressure between the upper and lower extremities In the presence of any degree of hypertension in the arms, palpation of femoral and dorsalis pedis arteries and checking the blood pressure in the legs must be a routine procedure

Cardiac anomalies associated with the adult type of coarctation are most frequently subaortic stenosis and occasionally a bicuspid aortic valve with or without aortic insufficiency In the presence of this first condition a loud, harsh systolic murmur is heard maximally to the right of the upper precordium transmitting into the neck Such associated anomalies do not contraindicate surgical intervention for the coarctation of the aorta

Anomalies of the Aortic Arch.—Anomalies of the aortic arch or subclavian arteries may cause pressure on the esophagus or trachea Abnormalities in the development from the primitive branchial arteries may result in a right aortic arch with descent either on the right or left side, a double aortic arch, or the right subclavian artery may take its origin from the left side of the aortic arch instead of branching from the innominate artery In certain circumstances both the trachea and esophagus are enclosed in a "vascular ring" An anomalous right subclavian artery passes posterior to and can compress the esophagus In these conditions the degree of pressure may be so slight that no symptoms develop and the anomaly is a chance finding on fluoroscopic or x-ray study or even at the autopsy table A certain number, however, may be so closely related to the esophagus or trachea as to create pressure conditions of serious import, especially in infants Symptoms noted are respiratory difficulty, stridor, and possibly cyanosis while feeding and difficulty in swallowing Repeated pulmonary infections may ensue

Clinical evaluation of these anomalies is made by study of the outline of the trachea and the barium-filled esophagus as seen in x-ray films taken in anterior and oblique or lateral views The ascending portion of a right aortic arch indents the right side of the esophagus as seen

FIG 4 Right aortic arch with descent on left Right anterior oblique view showing posterior impingement on esophagus

x-rays of the lung should be carefully studied and a search made over the lung fields for the presence of a brut Studies by angiocardiography are helpful in demonstrating and clarifying the presence of such an anomaly

Summary and Conclusions

Clinical evaluation of congenital anomalies of the heart and great vessels amenable to surgery have been presented Accurate diagnosis of these conditions is now of practical importance so that those cases where surgical therapy is available may obtain such benefits It is equally desirable that careful evaluation be made before discussion of operative therapy so that immediate false hopes may be avoided in cases not amenable to surgery at this time As further surgical procedures become available, continued refinements in clinical diagnostic methods will be necessary

THE USE OF CARDIAC CATHETERIZATION AND ANGIOCARDIOGRAPHY IN THE DIAGNOSIS OF CONGENITAL CARDIAC LESIONS

FREDERICK H KING, M D , New York City

(From the Cardiovascular Research Group of Mount Sinai Hospital)

WITH the development of successful surgical procedures for the correction of anatomic and physiologic abnormalities in the group of congenital cardiovascular lesions, differential diagnosis has assumed increased importance The usual methods of clinical examination, when they include a complete history, physical examination, fluoroscopy, electrocardiography, pulse wave tracings, and circulation time studies, admittedly furnish enough information on which to base a reasonably accurate diagnosis in the great majority of instances The emergence of specific criteria for operative intervention has pointed up the value of more accurate diagnosis, especially in instances where clinical data, as above outlined, are equivocal

In recent years cardiac catheterization and angiocardiography have been added to the methods previously employed Cardiac catheterization, first developed as a clinical method by Cournand and associates and utilized by others, aids in establishing the diagnosis by making possible the determination of the oxygen content of the blood from the great veins, pulmonary artery, and such cardiac chambers as may be reached with the catheter tip [1-3] It likewise allows for determination of the pressure within the right heart chambers and the pulmonary artery By simultaneously determining the oxygen consumption the application of the Fick principle makes possible, if desired, calculation of the cardiac output It is also possible to differentiate in certain abnormalities between the systemic and pulmonary blood flows and to estimate the volume of shunt per unit time from the venous to arterial side or vice versa These additional data may not be necessary in the majority of cases The value of catheterization in proving in difficult cases the existence of defects by passage of the catheter tip through them is self-evident The technic of cardiac catheterization has been amply described by Cournand, Bing, Dexter, and others and need not be further elaborated here [2-4] It is our routine procedure to follow catheterization immediately with angiocardiography by injecting the contrast medium through a cannula introduced into the antecubital vein from which the catheter has just been withdrawn.

Angiocardiography consists of the visualization of the cardiac chambers, the aorta, and pulmonary artery by the rapid introduction into the antecubital vein of radio-opaque fluid, such as 70 per cent diodrast, roentgen exposures thereafter being made in rapid succession This method, introduced as a routine procedure by Robb and Steinberg, has been employed with modifications in a systematic study of congenital cardiovascular lesions by Sussman and his associates [5-7]

Angiocardiography complements cardiac catheterization It furnishes a precise record in some instances of anatomic abnormalities not

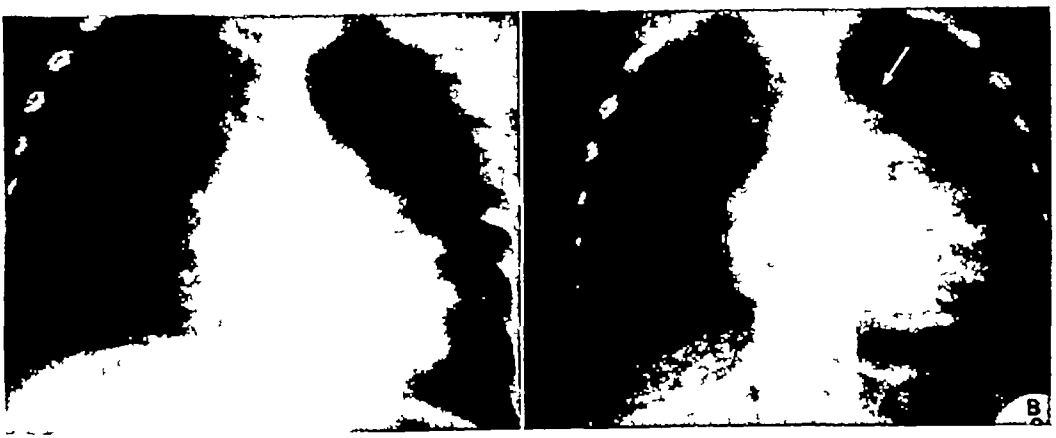
Presented at the 143rd Annual Meeting of the Medical Society of the State of New York Buffalo General Sessions May 6 1949
Aided by grants from the Linde Air Products Company and the Isaac Schneierson Foundation

normal in size, a raised and rounded apex, and concavity and absent pulsations instead of the normal convexity in the upper left third or pulmonary segment of the cardiac contour In the left anterior oblique view, abnormal clarity of the pulmonary window is frequently demonstrable In the right anterior oblique view convexity is noted at the level of the pulmonary segment Some variation of these findings is found in the presence of poststenotic dilatation of the pulmonary artery Although this condition may fill out the pulmonary segment to some degree and the shadow of the main branches is visible, there still will be no or only faint pulsations visible fluoroscopically in these areas Hilar vascular markings may be decreased but, in the presence of considerable compensatory bronchial circulation, may be normal in intensity Due to decreased pulmonary blood flow, the lung field, best checked in the x-ray, shows a rather striking clarity

A right aortic arch is associated with the tetralogy of Fallot in about one fifth of the cases It is important that the surgeon know prior to operation to which side the aorta arches This is demonstrated by x-ray study of the barium-filled esophagus as previously described

The electrocardiogram in practically all instances of the tetralogy of Fallot shows a marked degree of right axis deviation due to the right ventricular hypertrophy Compensatory polycythemia is the usual finding, the red blood count and hemoglobin ranging at times to extremely high levels Because of the overriding of the aorta, the arm-to-face circulation time is shorter than normal

Amelioration of the functional capacity in cases of the tetralogy of Fallot is accomplished by an operation to increase flow of blood to the lungs The procedure described by Blalock creates an anastomosis between a vessel from the aortic arch to the pulmonary artery [8] The Potts procedure creates a direct anastomosis between the aorta and the pulmonary artery [9]



Exact diagnosis in cases of cyanosis in infancy may be relatively difficult With cyanosis from birth the presence of transposition of the great vessels or a truncus arteriosus should be considered in differential diagnosis In these conditions the heart will usually increase considerably in size over the first few weeks of life in contrast to the relatively normal size maintained in the majority of cases of tetralogy of Fallot Analysis of the shadow of the great vessels is most helpful in differentiating in the anterior-posterior view between the wide shadow cast by a truncus arteriosus or the narrow shadow seen in instances of transposition of the great vessels In the latter case the shadow of the vessels is broader, as seen in the left anterior oblique view, and some degree of congestion of the lungs may be present Certain cases of transposition of the great vessels may survive into the childhood years if there are associated septal defects of sufficient size or patency of the ductus arteriosus to allow for appropriate and adequate shunts to support systemic and pulmonary circulation.

A clinical picture somewhat similar to the tetralogy of Fallot is presented by congenital tricuspid atresia or stenosis This malformation results in an underdeveloped right ventricle and associated pulmonary stenosis with decreased blood flow to the lungs Blood from the right auricle must escape through a widely patent foramen ovale or interauricular septal defect The important diagnostic features are the absence of enlargement in the region of the right ventricle, especially as noted in the roentgen left anterior oblique view, clear lung fields, and definite to marked left axis deviation in the electrocardiogram As these cases can be benefited by the Blalock or Potts procedures to increase blood flow to the lung, they should be considered as candidates for surgery [8 9]

The Eisenmenger complex may be present in cases where there is later development and milder degree of cyanosis than is usually seen in cases of tetralogy of Fallot Usually cyanosis appears in adolescence or early adult years A high interventricular septal defect and overriding of the aorta are present This syndrome differs from the tetralogy of Fallot in that there is no pulmonary stenosis but instead dilatation of the pulmonary artery This differential diagnosis is readily made by x-ray and fluoroscopy which show considerable increase in convexity and pulsation in the upper third of the left cardiac border and congestion of the lung fields due to increased pulmonary flow Cyanosis in these cases is partially the effect of admixture of arterial and venous blood in the overriding aorta but probably more in later life due to pulmonary vascular changes An operation to increase pulmonary flow is obviously contraindicated in the Eisenmenger complex

Instances of pulmonary stenosis, if associated with a right to left flow occurring through wide patency of the foramen ovale or an associated interauricular septal defect, will show cyanosis Cyanosis may be present early in life or develop in adult years Its appearance probably is related to onset of failure and increased pressure in the right auricle, which is seen to be enlarged on x-ray examination

Finally, cyanosis and clubbing may be an indication of the presence of an arteriovenous fistula in the lung As this relatively rare condition can be cured by surgical excision, the

FIG 2 (A) Posteroanterior roentgenogram showing globular-shaped heart with left ventricular enlargement

(B) Angiocardiogram in posteroanterior position showing concurrent visualization of right and left ventricles with visualization of aorta within two cardiac cycles after the right auricle.

reported that the appearance was consistent with the diagnosis of patent ductus arteriosus which had been considered as a tentative diagnosis by the referring clinic

Cardiac catheterization was performed The blood oxygen content of various samples was as follows

LOCATION	OXYGEN CONTENT (VOLUMES PER CENT)
Superior vena cava	9 1
Superior vena cava	9 4
Right atrium (high)	13 8
Right atrium (mid)	13 7
Right atrium (low)	13 6
Right ventricle	13 8
Oxygen capacity	15 8

The angiocardiogram showed considerable enlargement of the right ventricle and right auricle The left auricle was also distinctly enlarged The aorta was small The pulmonary artery was very much dilated (Fig 1B) On some of the roentgenograms there was a suggestion of continued visualization of the right auricle beyond the usual period of emptying

Comment.—In this case the history, the appearance of the conventional roentgenogram, and some of the physical findings were consistent with the diagnosis of patent ductus arteriosus However, the findings on the microplethysmogram did not support this impression The demonstration by angiocardiography of enlarged right heart chambers in addition to marked dilatation of the pulmonary artery and the suggestive continued visualization of the right auricle supported the diagnosis of interatrial septal defect The crucial demonstration of a marked increase of oxygen content of right auricular blood over that in blood samples obtained from the superior vena cava was unequivocal evidence of a shunt from the left atrium into the right via an interatrial septal defect

Attempts to catheterize the pulmonary artery in this case did not succeed, a difficulty which is encountered in about 25 per cent of our cases Thus it was not possible to obtain blood from the pulmonary artery and exclude the possibility of an associated patent ductus arteriosus

Case 2 Pulmonary Stenosis and Interatrial Septal Defect (*Diagnosis by Cardiac Catheterization and Angiocardiography—Corroboration at Autopsy*) —This was the first hospital admission of a twenty-two-month-old female At the age of one month she is said to have choked on her feedings She was thought to have an enlarged thymus for which she received radiotherapy A cardiac murmur was noted at this time. At the age of twelve months the child was hospitalized because of croup At this time the murmur was again noted, but there was no evidence of cyanosis The latter, as well as easy fatigability, were first noticed at the age of seventeen months Four months later the patient developed a cough and dyspnea on exertion It was noted that the finger nails were cyanotic at rest

She was an underdeveloped infant weighing 21 pounds The lips were intensely cyanotic The heart was enlarged to the left with a diffuse forceful apical impulse There was a loud, rough systolic murmur, most prominent in the third left intercostal space and transmitted over the entire precordium The liver was palpated two fingerbreadths below the costal margin The electrocardiogram disclosed right axis deviation. The findings in the precordial and unipolar limb leads were indicative of right ventricular hypertrophy The hemoglobin was 15 3 Gm , and there were present 7,000,000 red blood cells per cu mm. The rest of the blood count was within normal limits

Fluoroscopy and a routine roentgenogram showed the heart to be globular in shape with enlargement to the left (Fig 2A) The pulmonary artery and its branches were small The aortic knob was normal The barium-filled esophagus was not deviated The microplethysmogram gave no evidence of an extracardiac shunt.

A B

FIG 1 (A) Posteroanterior roentgenogram showing marked enlargement of pulmonary artery segment, dilatation of smaller pulmonary vessels, and enlargement of left ventricle.
(B) Angiocardiogram in oblique position showing enlargement of right auricle and right ventricle with marked dilatation of pulmonary artery

otherwise discernible These include abnormal position or size of great vessels and cardiac chambers, obstruction to flow of blood because of stenotic lesions in the outflow tracts of the heart or of the great vessels, and localized dilatation of the aorta caused by the infundibulum of a patent ductus arteriosus, as described by Steinberg, Grishman, and Sussman [8] Angiocardiography offers, in many instances, evidence of intracardiac shunts from right to left and vice versa Whereas catheterization yields more data relative to the dynamics of the circulation, angiocardiography furnishes information regarding the anatomic substratum as well as the dynamic sequelae The ability to delineate abnormalities beyond reach of the catheter tip and to portray defects involving no blood gas and pressure changes or changes too small to detect with catheterization are features of angiocardiography which give it added importance in the armamentarium employed in the diagnosis of congenital cardiovascular defects

Our experiences in the following cases are presented as illustrations of the use of these two methods when added to the usual clinical procedures A discussion of the difficulties and limitations encountered is also given.

Case Reports

Case 1 Interatrial Septal Defect (*Demonstration by Cardiac Catheterization*) —This patient was a twenty-two-year-old girl who was first found to have a heart murmur at the age of five For three months prior to admission she noticed palpitation on exertion and for three weeks left anterior chest pain, radiating into the left arm She had dyspnea on climbing stairs. She had never noted cyanosis There was *no history of rheumatic fever*

She was a well-developed girl. The lungs were clear The heart was enlarged. The point of maximal impulse was 2 cm to the left of the midclavicular line in the fifth interspace. There was a blowing systolic murmur heard all over the precordium A short presystolic sound was audible at the apex The pulmonic second sound was louder than the aortic There were frequent extrasystoles with occasional bigeminal rhythm The blood pressure was 104/70 The electrocardiogram showed right axis deviation, prominent P waves, depression of RST_2, RST_3, and RST_4, semi-inverted T_1 and inverted T_4 There was bigeminal rhythm due to recurrent premature beats The blood count was normal. The circulation time with calcium gluconate was twelve seconds and with ether seven seconds The venous pressure was 8 cm with no rise on pressure over the right upper quadrant Micropleth ysmogram from the left index finger did not conform to the pattern usually seen with patent ductus arteriosus

Posteroanterior roentgenogram of the chest showed marked enlargement of the pulmonary artery segment (Fig 1A) The aortic knob was small The left ventricle appeared enlarged. The smaller pulmonary vessels in both lungs were distended Fluoroscopy showed no *displacement of* the barium-filled esophagus The roentgenologist

At a second operation the ductus was successfully ligated. The ductus was found to be short, almost constituting a direct arteriovenous fistula.

Comment.—In this patient the correct diagnosis of patent ductus arteriosus was made at the first admission on the basis of clinical findings and angiocardiography alone On the second admission catheterization was also performed Although quantitative estimation of the volume of the shunt was not attempted, the marked dilatation of the pulmonary artery and left heart chambers, the continuous presence of diodrast in the pulmonary artery, the wide peripheral pulse pressure, the high pressure in the pulmonary artery (mean pressure, 51 mm. mercury and pulse pressure, 14 mm mercury), and the markedly elevated oxygen content of the blood in the pulmonary artery, compared with that *in the right ventricle, were all indicative of a large* shunt from the aorta into the pulmonary artery

Case 4 Subacute Bacterial Endocarditis Engrafted Upon Rheumatic Heart Disease with Aortic Stenosis and Insufficiency (*Exclusion by Catheterization of Recanalization of Previously Ligated Ductus Arteriosus*) —This patient was a nineteen-year-old woman who was first admitted with a history of nocturnal dyspnea since the age of three years A heart murmur had been detected at the age of three Recently, she had complained of precordial distress on exertion

The patient appeared chronically ill and was mildly febrile The liver and spleen were palpable The heart was enlarged, the apex extending to 3 cm beyond the midclavicular line A systolic pulmonic thrill was present Loud pulmonic systolic and diastolic murmurs were audible, and these were widely transmitted over the precordium The blood pressure was 110 systolic and 50 diastolic The circulation time with calcium gluconate was seven seconds, while the ether circulation time was two seconds The venous pressure was 10 cm of water rising to 14 cm on pressure over the right upper quadrant The electrocardiogram showed left axis deviation and no other abnormalities Roentgen examination of the heart including fluoroscopy showed straightening of the left cardiac border The heart was moderately enlarged to the left and slightly to the right The microplethysmogram was interpreted as indicating an extracardiac arteriovenous shunt

On the basis of the character and location of the murmurs, the cardiac contour on x-ray examination, the large pulse pressure, and the microplethysmogram, a diagnosis of patent ductus arteriosus was made, and ligation of the ductus was advised.

At operation the heart was found to be enlarged The ductus was of large caliber and was tied at each extremity by many silk ligatures Immediately after ligation the thrill disappeared, and the heart rate slowed perceptibly The patient's temperature declined to normal on the third postoperative day and remained normal until discharge Before discharge it was noted that a diastolic pulmonic murmur was still present, but this was much less intense than before operation The significance of this residual murmur was not clear Such possibilities as dilatation of the pulmonic ring or an associated aortic insufficiency were suggested The patient was discharged to a convalescent home

Following operation the patient had pronounced dyspnea and palpitation on walking or climbing stairs Her physician noted the reappearance of a continuous murmur, and the patient began to have irregular fever She was therefore readmitted to the hospital about four weeks after discharge

At this time the patient had mild fever The lungs were clear Examination of the heart now disclosed a systolic thrill and murmur over the aortic area and in the neck. A diastolic murmur to the left of the sternum near the pulmonic area was audible, and at this site a diastolic thrill was palpable The blood pressure was now 130 systolic and 0 diastolic

Because of the fever and the reappearance of a *systolic and diastolic murmur, it was suggested that* recanalization of the ligated ductus arteriosus must have occurred and that there might be an associated subacute bacterial endocarditis involving the ductus or right side of the heart However, the peripheral vascular phenomena such as collapsing pulse, wide pulse pressure, the character and localization of the murmurs carefully studied by phonocardiography, and the "pistol shot" brachial pulse led some observers to suggest that a likely possibility was aortic stenosis and insufficiency with superimposed subacute bacterial endocarditis Peripheral venous blood cultures were consistently negative

It was important to resolve this difference of opinion, since recanalization of the ductus and associated subacute bacterial endocarditis would be an indication for reoperation At this point the patient was subjected to cardiac catheterization

The oxygen content of blood samples obtained at catheterization were as follows

Location	Oxygen Content (Volumes Per Cent)
Right pulmonary artery	7 7
Main pulmonary artery	7 4
Right ventricle	7 3
Right ventricle	7 9
Right atrium	7 1
Superior vena cava	7 0
Oxygen capacity	11 0

A blood sample from the right pulmonary artery was obtained for culture This disclosed a contaminant only

The findings at catheterization excluded a significant arteriovenous shunt into the pulmonary artery A diagnosis of bacterial endocarditis engrafted upon rheumatic heart disease with aortic stenosis and insufficiency was made The patient subsequently developed petechiae and other embolic phenomena After many negative blood cultures one yielded Streptococcus viridans in one flask. The patient was given routine penicillin therapy for the next eight weeks with recovery from the infection There was no significant alteration, however, in the cardiovascular phenomena described

Comment.—In this instance it was not possible from physical signs alone to differentiate with certainty between aortic disease with superimposed bacterial endocarditis and a recanalized ductus arterio-

Cardiac catheterization was performed through the right saphenous vein A number 7 catheter was passed up through the inferior vena cava into the right atrium and then into the right ventricle At the region of the outflow tract of the right ventricle the catheter tip seemed arrested and could not be passed into the pulmonary artery nor could it be passed into the aorta The catheter was then withdrawn into the right atrium again It was then advanced across the heart shadow toward the left border at a more cephalad level than previously It was thought to have passed through an interatrial septal defect into the left atrium The oxygen content of the blood samples were as follows

Location	Oxygen Content (Volumes Per Cent)
Right atrium	8 2
Left atrium	12 4
Right ventricle (mid)	8 8
Right ventricle (outflow tract)	8 5
Inferior vena cava	9 2
Left femoral artery (done day after catheterization)	10 8
Oxygen capacity	18 9
Percentage saturation	57

The angiocardiogram demonstrated an interatrial septal defect The left atrium visualized almost simultaneously with the right The aorta was visualized within two cardiac cycles after the right auricle (Fig 2B) The right ventricle and the pulmonary artery were dilated It was impossible to determine whether diodrast had reached the aorta by passing through the left atrium and left ventricle or from the right ventricle by way of an overriding aorta

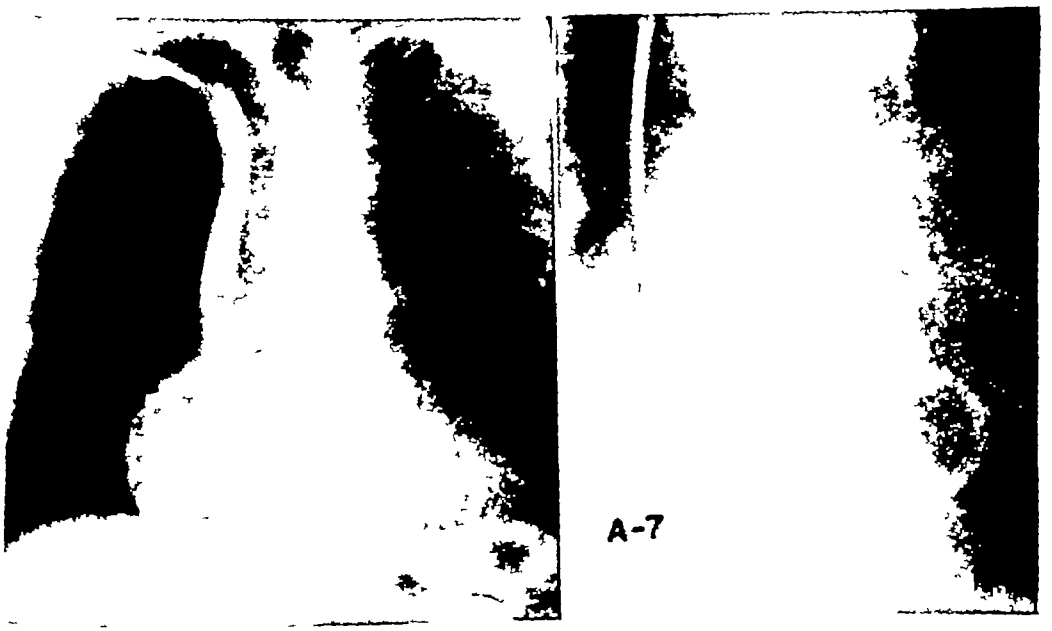
The child developed mild diarrhea Her condition grew worse, and she finally died in coma, three weeks after admission Postmortem examination demonstrated the presence of a large interatrial septal defect and valvular pulmonary stenosis with dilatation of the pulmonary artery The right ventricle and atrium were hypertrophied The ductus arteriosus was obliterated

Comment.—This is a case of pulmonary stenosis associated with an interatrial septal defect The presence of the septal defect was determined in vivo by the passage of the catheter through the defect into an area later shown by angiocardiography to be the left atrium This was corroborated by the distinctly higher oxygen content of the blood obtained from the left atrium than from the right Final confirmation of a defect was obtained by the fact that the left atrium opacified immediately after the right atrium

Inability to catheterize the pulmonary artery with the catheter plainly in the outflow tract of the right ventricle was suggestive of pulmonary stenosis as was the absence of forceful pulsations at the pulmonary artery segment on fluoroscopy Pressure determinations were not made because of technical difficulties, but these would have been valuable only if the pulmonary artery had been catheterized and a differential in pressure between the artery and the right ventricle in favor of the latter had been demonstrated

In this case the possibility of an overriding aorta could not be excluded by angiocardiography, since both an interatrial shunt from right to left and an overriding aorta lead to early opacification of the aorta An overriding aorta is infrequently demonstrated at catheterization when it is found possible to advance the catheter tip from the right ventricle into the aorta, but this was not possible in the case just detailed Both angiocardiography and catheterization may, therefore, be unsuccessful in differentiating between pulmonary stenosis associated with interatrial septal defect, as in this instance, and tetralogy of Fallot in which a patent interatrial septal defect is an added anomaly

Case 3 Typical Patent Ductus Arteriosus (*Cardiac Catheterization and Angiocardiographic Findings*) —This patient was a twenty-three-year-old man who was first admitted to the Mount Sinai Hospital in 1946 At that time he gave a history of a cardiac murmur since birth He complained of the recent development of dyspnea, palpitation, and tachycardia on exertion



The cardiac findings were as follows The heart was enlarged, the point of maximal impulse being in the midaxillary line There was a marked systolic thrill which was most prominent over the third interspace to the left of the sternum In this area there was a loud systolic murmur followed by a faint diastolic murmur The blood pressure was 135 systolic and 45 diastolic The electrocardiogram showed changes seen in generalized enlargement without special axis deviation A routine roentgenogram showed an enlarged heart with dilated pulmonary artery An angiocardiogram disclosed an enlarged left atrium and left ventricle and dilated pulmonary artery with relatively little dilatation of the right heart

On the basis of these findings an exploratory thoracotomy was performed for ligation of a patent ductus arteriosus Ligation was attempted, but because of technical difficulties it was abandoned

The patient was readmitted about two years later The physical and routine roentgen findings were the same as before Cardiac catheterization was performed and followed by angiocardiography The blood oxygen findings at catheterization were as follows

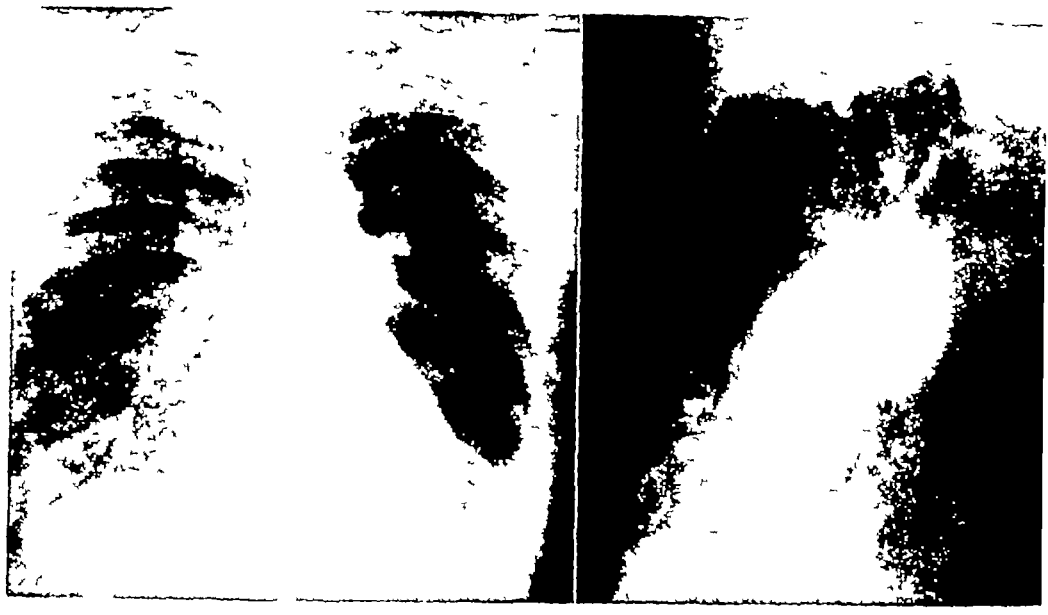
Location	Oxygen Content (Volumes Per Cent)
Right ventricle	11 1
Right ventricle	11 2
Right pulmonary artery	17 0
Main pulmonary artery	14 6
Right brachial artery	18 6
Oxygen capacity	19 7
Percentage saturation	94

The angiocardiogram showed an extremely dilated pulmonary artery The aorta did not visualize well The descending aorta did not visualize at all There was diodrast continuously in the pulmonary artery The left heart was markedly enlarged

A B

FIG 4. (A) Angiocardiogram in posteroanterior position showing diodrast entering right auricle from superior vena cava with division of stream of diodrast to outline filling defect in right auricle (B) Spot film showing catheter coiled within right auricle Catheter tip reached to outer limit of "juxtacardiac shadow" showing it to be part of the heart

close any of the usual causes of pulmonary artery enlargement The oxygen content of the blood from the right heart and pulmonary artery and the pressures in these areas showed no evidence of a shunt The mean pressure in the right ventricle was 10 mm. of mercury and that in the left pulmonary artery 15 mm. of mercury, which we considered within normal limits with our apparatus Pulse tracings were not sufficiently satisfactory to justify an analysis but indicated that pulse pressures also were of a normal order There was no electrocardiographic evidence of right axis deviation The angiocardiogram showed no enlargement of the right heart chambers and no evidence of an intracardiac shunt Within the limits of our diagnostic aids, then, it is possible to exclude such causes of pulmonary artery enlargement as patent ductus arteriosus, interatrial septal defect, Eisenmenger complex, and mitral stenosis The negative serology and normal contour of the ascending aorta strongly militate against the remote possibility of syphilitic aneurysm of the pulmonary artery It seems, in the light of these facts, a fair presumption, therefore, that this is a case of idiopathic dilatation of the pulmonary artery



Case 6 Aneurysm of the Right Sinus of Valsalva (*Demonstration by Angiocardiography*) —This was the first hospital admission of a thirty-four-year-old white woman whose chief complaint was repeated small hemoptysis for one and a half years There was no associated cough, chest pain, night sweats, or fever There was no history of tuberculosis contact Because of the persistently recurring hemoptysis chest x-rays were taken These are said to have disclosed "a mass in the right lung field near the heart The only relevant facts in her past history were that a heart murmur was discovered ten years before and that hypertension was known for four or five months

The patient was a rather small, although well-developed female The heart percussed enlarged The point of maximal impulse was in the fifth intercostal space outside the midclavicular line The first sound at the apex was accentuated The aortic second sound was greater than the pulmonic. At the apex there was present a soft systolic murmur In the fourth intercostal space to the right of the sternum there was audible a to-and-fro systolic-diastolic murmur which was transmitted up the sternum The blood pressure was 186 systolic and 90 diastolic There was no decrease of pressure in the lower extremities The lungs were clear

The electrocardiogram showed left axis deviation T_3 was inverted, and T_4 was diphasic, suggesting a transverse position of the heart

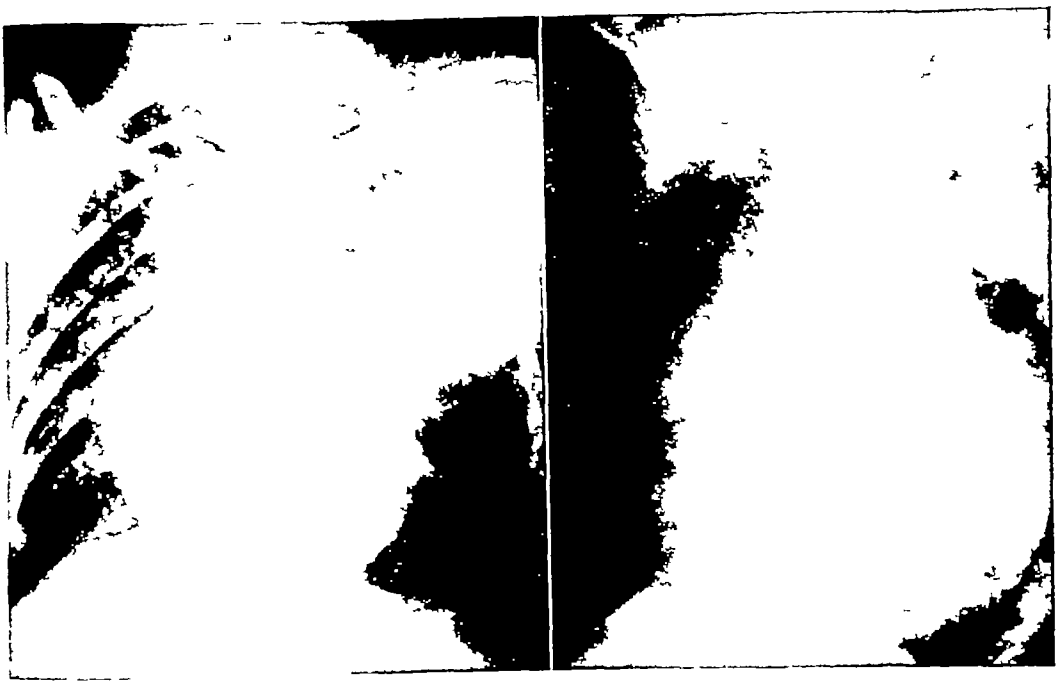
X-ray of the chest disclosed a globular mass in the lower right chest which could not be separated from the heart shadow Electrokymographic studies revealed the mass to pulsate actively

During cardiac catheterization it was noted, first, that the catheter tip reached to the outside limit of the shadow in the right chest, indicating definitely that it was part of the heart mass (Fig 4B) Second, it was observed that there was unusual difficulty in passing the catheter tip through the right auricle and into the right ventricle The significance of this observation was not clear at the time It was only clarified when the angiocardiograms were studied

A B

FIG 3 (A) Posteroanterior roentgenogram of chest showing marked prominence of pulmonary artery segment and slight enlargement of left ventricle
(B) Angiocardiogram in oblique position showing marked dilatation of pulmonary artery

sus with infective endocarditis This case illustrates the value of cardiac catheterization in excluding the canalization of a previously ligated ductus arteriosus The demonstration that the oxygen content of the blood throughout the lesser circulation was more or less constant was cogent evidence against a significant shunt through a recanalized ductus arteriosus Furthermore, the result of the culture of blood obtained from the right pulmonary artery gave some reason to believe that an infection of the right side of the heart, not detectable from peripheral venous blood culture, was not being overlooked In this instance the findings obtained at catheterization were of practical importance They precluded reoperation and, by exclusion, led to the correct diagnosis and therapy



Case 5 Idiopathic Dilatation of the Pulmonary Artery (*Diagnosis by Exclusion, Using Cardiac Catheterization and Angiocardiography*) —This patient was a forty-eight-year-old Negro woman sent to the cardiac clinic of the outpatient department because of the detection of a murmur ascribed to congenital heart disease Except for vague chest pain she had no significant complaints There was no history of rheumatic fever or of any of its manifestations in childhood

Physical examination disclosed no abnormalities other than those related to the heart The apex beat was not easily felt The sounds were of fair quality Over the midsternal region a short soft systolic murmur and a long moderately harsh diastolic murmur were audible Both were transmitted radially to the entire precordium. The blood pressure was 130 systolic and 80 diastolic The blood Wassermann reaction was negative. Roentgen examination of the heart including fluoroscopy showed the left ventricle to be somewhat rounded and broadened (Fig 3A) There was no evidence of enlargement of the right ventricle or either auricle The pulmonary artery appeared dilated and hyperdynamic The electrocardiogram was normal and showed no axis deviation. A phonocardiogram disclosed the presence of a low amplitude systolic murmur of high frequency components at the pulmonic area. The second sound at the pulmonic area was of high amplitude and was followed by a descrescendo diastolic murmur of high frequency components and moderate amplitude, the latter considered consistent with a Graham Steel murmur

On angiocardiography the pulmonary artery was found to be considerably dilated (Fig 3B) The right side of the heart was normal The left ventricle was perhaps slightly dilated The left auricle did not visualize clearly The ascending aorta was normal in outline Cardiac catheterization was performed and the blood oxygen findings were as follows

LOCATION	OXYGEN CONTENT (VOLUMES PER CENT)
Superior vena cava	11 6
Right auricle	11 6
Right auricle	11 5
Right ventricle	11 1
Right ventricle	10 7
Left pulmonary artery	11 1
Right brachial artery	15 4
Oxygen capacity	16 1
Percentage saturation	96

Comment —The central feature of this case is dilatation of the pulmonary artery The findings on catheterization and angiocardiography failed to dis-

A B

FIG 5 (A) Posteroanterior roentgenogram showing enlargement of left ventricle Conformation and position of heart shadow altered by chest conformity
(B) Angiocardiogram in oblique position showing stenosis of descending aorta with poststenotic dilatation

and a half years he was hospitalized because of generalized edema and was treated for decompensation with digitalis He improved rapidly and was maintained on digitalis until the age of six Since then there had been no evidences of diminished cardiac reserve Six weeks before admission he returned from summer camp where he had been well and had participated in all camp activities He developed a sore throat on his return, was treated with sulfonamides for three days, and recovered. One week later he again became febrile, and, when there was no response to sulfa drugs, he was admitted to the hospital

He was a thin, moderately well-developed, adolescent male, febrile, and appearing acutely ill. There were signs of a bronchopneumonia at the left base which apparently accounted for the fever which subsided spontaneously after five days His cardiac findings attracted clinical interest The heart was enlarged to the left and to the right There was a loud blowing systolic murmur over the entire precordium which was loudest in the fourth intercostal space just to the left of the sternum The pulmonic second sound was accentuated The blood pressure in the left arm was 140/84 and in the left leg 130/80 The electrocardiogram revealed unusual axis deviation RST_1, RST_2, and RST_3 were slightly depressed P waves were prominent T_2 was diphasic, and T_3 was inverted The character of the electrocardiogram, including precordial leads, suggested hypertrophy of the ventricles with clockwise rotation of the heart The venous pressure and circulation times were normal

The phonocardiogram showed a systolic murmur composed of high-frequency components, recorded maximally at the fourth and fifth intercostal space to the left of the sternum. The pulmonic second sound was of high amplitude

The carotid and venous pulses were normal Simultaneous recordings of the radial and femoral pulses indicated a delay in pulse wave transmission to the lower extremities

Microplethysmographic studies of the left index finger and the left great toe showed normal volume-pulse relationships The pattern did not resemble that seen in patent ductus arteriosus

A routine chest film showed enlargement of the heart to the right and left (Fig 5A) The apex of the left ventricle was very much rounded The root of the pulmonary artery appeared large

Two attempts at catheterization were unsuccessful because of local venospasm.

The angiocardiogram showed moderate dilatation of the right auricle (Fig 5B) The right ventricle was slightly dilated and displaced to the right The pulmonary artery was dilated The left auricle was of normal size The left ventricle was markedly enlarged The aorta showed a definite coarctation just beyond the aortic arch with poststenotic dilatation There was no evidence of an intracardiac shunt

Comment.—This patient, strongly suspected of having a congenital defect, could not be catheterized because of technical difficulties Routine physical examination gave no definite evidence of the nature of the disorder Delay of femoral pulse transmission was evidence in favor of a stenotic lesion along

The blood oxygen findings were as follows

Location	Oxygen Content (Volumes Per Cent)
Superior vena cava	8 7
Right atrium	11 9
Right ventricle (high)	12 4
Right ventricle (low)	11 8
Pulmonary artery	11 5
Inferior vena cava	12 6
Brachial artery	15 0
Oxygen capacity	16 1
Percentage saturation	93

The angiocardiogram, done immediately after catheterization, showed the radio-opaque fluid to enter the right auricle and then divide into two streams surrounding a filling defect within the right auricle (Fig 4A) This filling defect was identified in subsequent exposures as a mass indenting the right auricle which became opaque at the same time as the aorta This suggested strongly that the mass was an aneurysm of the right sinus of Valsalva The mass did not empty as rapidly or as easily as the aorta It was significant that there was a faint continued density in the heart throughout most of the observations so that a perforation of the aneurysm into one of the right heart chambers might be present The left ventricle was dilated The remaining chambers and the pulmonary artery were not abnormal The aorta was noted to be irregular in outline

The opinion of the surgeons was that, because of the location, wiring this aneurysm would be a hazardous procedure The patient was therefore discharged from the hospital

Comment.—This is an instance where the angiocardiogram furnished a precise portrayal of an anatomic abnormality which would have not otherwise been obtainable It was in this case indispensable to the diagnosis

Because of the pronounced difference in oxygen content between the superior and inferior vena cava, it was not possible from the oxygen determinations to state that a shunt from the aneurysm into the right auricle or ventricle existed. The intracardiac pressure tracings, taken within the right heart chambers, were within normal limits which was evidence against any significant shunt, even though this diagnosis was suggested by the murmurs

Case 7 Double Superior Vena Cava in a Case of Tetralogy of Fallot (*Demonstration by Angiocardiography*) —This patient was a seven-year-old Negro girl with a history of cyanosis and exertional dyspnea since the age of ten months For several months before admission her dyspnea had become more pronounced She became chronically fatigued and her activity became very limited There was no history of peripheral edema

The child was poorly developed She was frequently found in a squatting position in bed There was a dusky hue to the nailbeds and cyanosis of the mucous membranes Mild clubbing of the fingers was present The heart was enlarged to percussion, as was the area of the superior mediastinum. The heart sounds were of good quality A loud, coarse, high-pitched systolic murmur was heard with maximal intensity in the second left interspace at the left sternal border In this area a systolic thrill was palpable The lungs were clear The liver and spleen could not be felt The hemoglobin was 12 5 Gm, the blood count being essentially normal

Roentgen examination of the chest showed enlargement of the heart to the right with marked rounding of the right cardiac contour in the left oblique position indicating considerable enlargement of the right ventricle The root of the pulmonary artery was not well delineated The superior mediastinal shadow was wide

Attempts at catheterization were unsuccessful because of inability to advance the catheter tip into the superior vena cava despite persistent effort. The oxygen content of the arterial blood was 12.6, the oxygen capacity 20 4, and the percentage saturation 61 8 volumes per cent

On angiocardiography, performed through the right antecubital vein, the following observations were made There was evidence of pulmonary stenosis, the pulmonary valve and the base of the main pulmonary artery being very narrow There was also evidence of an overriding aorta, there being very early opacification of the aorta It seemed likely, also, that there was an interventricular septal defect On some of the films there was a suggestion of flow of diodrast from the right atrium into the left, which would indicate an associated interatrial septal defect, but this was not conclusive The width of the superior mediastinum was explained in part by the demonstration of a dilated superior vena cava. However, it was noted that the left border of the superior mediastinum extended beyond any demonstrated vascular structure The possibility of a second superior vena cava on the left side to account for this shadow was suggested

A second angiocardiogram was done, the contrast medium being injected into the left antecubital vein. This demonstrated conclusively the existence of a second superior vena cava and accounted fully for the left portion of the wide superior mediastinal shadow

This patient had a Blalock procedure performed at another hospital at which time these findings were confirmed The patient was seen six months after operation when she was much improved

Comment —This case illustrates the value of angiocardiography where catheterization through the upper extremity was impossible because of sharp angulations at the junctions of the subclavian veins and the superior vena cavae. It was possible by angiocardiography alone to demonstrate the essential characteristics of the tetralogy of Fallot Furthermore, it conclusively elucidated the anatomy of the wide superior mediastinal shadow Once these facts had been satisfactorily ascertained, it seemed unnecessary, for diagnostic purposes only, to subject the patient to still another catheterization via the saphenous vein

Case 8 Coarctation of the Aorta (*Demonstration by Angiocardiography*) —This was the first hospital admission of a sixteen-year-old boy who was known to have an enlarged heart and a murmur since in fancy He was never cyanotic At the age of two

cially of the left side Hypertrophy frequently gives way to dilatation with diminishing ability of the heart to maintain its constant, heavy load Thus, varying degrees of circulatory insufficiency ensue In the latter connection, it is obvious that the longer the heart is subjected to great strain, the greater are the chances that cardiac failure will supervene Thus the likelihood of cardiac failure increases with age The final factor to be considered in the production of cardiac failure is the physical activity of the patient During infancy, when the child sleeps a large part of the time and does not walk, minimal circulatory demands are made upon the heart As the child grows older and begins to walk, and then to run and jump during play, the cardiac load becomes increasingly greater Thus, with ever-increasing circulatory demands being made upon the heart, the likelihood of cardiac failure grows greater

Retardation of growth and development appears, in general, to be directly proportional to the diameter of the open ductus As mentioned previously, the greater the diameter of the ductus, the greater is the "leakage" from the aorta into the pulmonary artery The greater the leakage from the aorta, the less is the peripheral blood flow Since physical growth is dependent upon adequate nourishment of all of the tissues of the body by arterial blood, it is apparent that significant retardation of growth must be the inevitable accompaniment of diminished peripheral blood flow It is interesting to note that, in many instances, a child with a patent ductus may grow and develop normally In such cases, at operation, I have invariably found the ductus to be relatively small Similarly, when symptoms of circulatory insufficiency have been absent, other factors being equal, the most common finding at operation has been a ductus of relatively small caliber

In 1940, the author and Vesell added another indication for operation in cases of patent ductus arteriosus, e g , subacute bacterial endarteritis [3] This additional operative indication has stood the test of time and has taken its place beside those already mentioned [4] Thus, all clinicians appear presently to be in agreement concerning the wisdom of operation upon children who present evidence of circulatory insufficiency, retarded physical development, and infection of the ductus However, there appears to be a widely held view that, once an individual with patent ductus arteriosus has passed safely through childhood into adolescence and adult life, his future is secure and his life expectancy as great as that of his neighbor It is natural that pediatrists, observing certain children with patent ductus leading normal lives and apparently unhandicapped, should assume that such individuals remain well after leaving their care Personal observation of a substantial group of adults with patent ductus arteriosus has convinced the author that such not only is not necessarily the case but also is rather unusual Indeed, such a state of affairs is so uncommon that when an adult with patent ductus lives to a ripe old age, it usually constitutes an occasion for reporting the case in detail

Turning now to adults suffering from patent ductus, failure of normal growth and physical development may at once be eliminated as an indication for operation The reason for the foregoing, obviously, is that by the time the patient has reached adult life he has ceased growing Under such circumstances, operative treatment cannot be expected to result in further growth of bodily structures which have already attained their maximum size Thus, in adults there remain only two indications for operation, namely, circulatory failure and subacute bacterial endarteritis

In the author's experience, circulatory failure is a much more common complication among adults than among children As stated previously, the factors responsible for cardiac failure are (1) the diameter of the ductus, (2) the physical activity of the patient, and (3) the duration of the lesion. Assuming that a ductus is of identical size in a child and an adult, it is apparent that the usually greater physical activity of an adult as compared with that of a young child imposes a greater strain upon the heart of the former and constitutes one of the factors responsible for the higher incidence of cardiac failure among patients in the older age groups In considering the duration of the lesion as a factor responsible for cardiac failure, it is apparent that duration, as measured in terms of age of the patient, constitutes one of the most important factors that operates to produce circulatory failure with frequency in adults Since continued cardiac strain is an important factor leading to cardiac breakdown, it is natural that the older the patient with a patent ductus, the greater the likelihood of circulatory failure And finally, in adults an additional factor comes into play I refer specifically to myocardial degeneration The latter may be considered to be almost a "normal" development in adults In young children and adolescents in general, the myocardium is of excellent "quality" Translated into practical terms this implies good cardiac reserve With the passage of years, so-called "normal" degenerative changes occur The latter include fatty infiltration and fibrous degeneration As a result of these degenerative changes, the ability of the heart to withstand the continuously heavy load imposed upon it by the presence of the patent ductus eventually becomes lessened The result

the greater circulation Angiocardiography furnished precise delineation of the defect by demonstrating a typical coarctation of the aorta with poststenotic dilatation

In the absence of oxygen determinations obtained at catheterization, it is not possible to exclude completely the possibility of an associated patent ductus arteriosus However, the nature of the murmurs as recorded by phonocardiography and the plethysmographic findings make such a possibility seem remote

Summary

1 A group of cases is presented to illustrate the integrated use of cardiac catheterization and angiocardiography in the diagnosis of congenital cardiac lesions

2 The limitations of the procedures and the difficulties encountered are discussed

THE INDICATIONS FOR OPERATION IN PATENT DUCTUS ARTERIOSUS (WITH SPECIAL REFERENCE TO ADULTS)

Arthur S W Touroff, M D , F A C S , New York City

(*From the Surgical Service of Mount Sinai Hospital*)

A NEW era in cardiovascular surgery began in 1939 when Gross and Hubbard reported the first successful ligation of a patent ductus arteriosus [1] During the decade that has elapsed since then, surgery has become firmly established as the sole definitive form of therapy for this congenital cardiovascular anomaly The general acceptance of surgical therapy at the present time is based upon the clear demonstration that, in the hands of experienced surgeons, the morbidity and mortality of operation is negligible as compared with the morbidity and mortality of the disease when the latter is permitted to go untreated

Ductal interruption by ligation or division is a truly corrective procedure in the sense that the surgeon is able to accomplish that which nature failed to do for the patient in the neonatal period (This is in contrast to a procedure such as the Blalock operation for the tetralogy of Fallot, in which the existing anatomic defects within the heart are not corrected but an additional anomaly added in order to ameliorate or eliminate certain serious and disabling symptoms) The value of operation in patent ductus arteriosus has long since been demonstrated so conclusively that any communication dealing with the subject appears to be almost superfluous However, relatively little attention appears to have been paid to the problem of patent ductus arteriosus in adults The personal experience of the author has led him to the conclusion that the latter often constitutes a much more serious lesion than patent ductus in children. Accordingly, it is the purpose of this communication to review the indications for operation and to stress especially the wisdom of operation in adults

The indications for operation in children, as originally set forth by Gross, were circulatory insufficiency and retardation of normal growth and development [2] The age at which circulatory failure supervenes during childhood may be considered to depend essentially upon three factors The first factor is the actual diameter of the open ductus, the second is the duration of the lesion, or, in other words, the age of the patient, and the last is the physical activity of the patient In the presence of an open ductus, blood flows continuously from the aorta into the pulmonary artery This is so because, regardless of the phase of the cardiac cycle, the pressure of blood within the aorta is higher than the pressure of blood within the pulmonary artery As a result of "leakage" of blood from the aorta into the pulmonary artery, the amount of blood which flows into the aorta beyond the site of the "leak" (patent ductus) is reduced significantly In order to maintain an adequate peripheral circulation in the presence of such a leak, the cardiac rate speeds up, and cardiac output is thereby increased The inevitable result of the increased activity of the heart—which perforce must continue uninterruptedly, day and night—is cardiac hypertrophy, espe-

Presented at the 143rd Annual Meeting of the Medical Society of the State of New York Buffalo General Sessions May 6 1949

active, the incidence of circulatory insufficiency increases. Furthermore, the incidence of subacute bacterial endarteritis also increases significantly Once the child enters school, operation should be considered one of "necessity"

Once the patient has reached adolescence or adult life, the incidence of circulatory insufficiency and infection becomes appreciably greater In fact, these complications become almost inevitable with the passing years Furthermore, operation becomes increasingly difficult and dangerous as the patient grows older During adolescence and adult life, the indication for operation becomes "urgent"

In order to illustrate some of the points which have been made, the following case of patent ductus arteriosus in an adult is presented

Case Report

F S, a married white woman, aged twenty-six, was admitted to the surgical service of the author at Mount Sinai Hospital on May 6, 1948, with the chief complaint of shortness of breath and easy fatigability of ten months duration When she was one week old, her parents were told that she had a "congenital cardiac lesion." During her entire life she adhered to a regime of restricted physical activity and, aside from scarlet fever at the age of five, remained relatively well.

At the age of twenty-two, the patient married, two years later she became pregnant During the first four months of pregnancy she was quite well but at the end of that period began to suffer from malaise, easy fatigability, shortness of breath, and fever Temperature, which at first was mild, gradually became higher and more septic in type Concomitantly, the patient began to lose weight and became anemic Shortly thereafter, sweats and intermittent chills were noted. The clinical diagnosis of patent ductus arteriosus with superimposed subacute bacterial endarteritis was then made, the presence of infection being confirmed by blood cultures which revealed scattered colonies of Streptococcus viridans.

The patient was placed on massive doses of penicillin and, soon thereafter, blood cultures became sterile For the remaining five months of her pregnancy, she was maintained on intensive penicillin therapy Repeated blood cultures taken during that period remained sterile Her general condition gradually improved, and she was delivered of a normal infant at term. Penicillin therapy then was discontinued, the patient remaining well thereafter until approximately ten months prior to her admission

Ten months preceding admission, she began to suffer from palpitation and "heart consciousness" At the same time, she became progressively short of breath, even on walking slowly Marked fatigue reappeared Examination by her family physician disclosed marked enlargement of the heart and tachycardia. Accordingly, she was subjected to detailed study

FIG 1 Preoperative film of chest Note marked cardiac enlargement, prominence of pulmonary artery segment and bilateral pulmonary vascular congestion.

On physical examination, the patient was noted to be of slight stature Blood pressure was 112/40 Pulse rate was 110 at rest. The significant physical findings were confined to the heart. On auscultation, a loud machinery murmur with systolic accentuation was heard over the third interspace immediately to the left of the sternum. The murmur was transmitted for a short distance upward and downward, along the edge of the sternum. It also was audible in the left interscapular area. A coarse systolic thrill was palpable in the third left interspace close to the edge of the sternum.

The electrocardiogram revealed evidence of left ventricular preponderance. X-ray examination of the chest revealed the heart to be considerably enlarged, especially toward the left. The pulmonary artery segment was unusually prominent. Bilateral pulmonary vascular congestion was present (Fig 1) On fluoroscopy marked pulsation of the pulmonary artery (hilar dance) was noted Angiocardiography disclosed the presence of a greatly enlarged pulmonary artery and dilatation of the left ventricle A localized dilatation of the aorta was noted at the point where the aorta and pulmonary artery tended to approximate one another The microplethysmographic tracings were characteristic of an arteriovenous shunt (extracardiac) such as we have noted in cases of patent ductus A phonocardiographic tracing revealed the presence of a continuous, rough murmur which was loudest over the third left interspace immediately to the left of the sternum. The murmur was both systolic and diastolic in time but was accentuated during systole On the basis of the foregoing clinical and laboratory findings, the diagnosis of patent ductus arteriosus with circulatory insufficiency was made and operation advised

The patient was admitted to Mount Sinai Hospital on May 6, 1948, and operation performed the following day under ethylene-ether-oxygen anesthesia. A left submammary incision was made and the breast mobilized in an upward direction The

is circulatory failure of varying degree In our own experience, we have observed this complication with increasing frequency as patients entered the third, fourth, and fifth decades of life Incidentally, our oldest patient with cardiac failure was sixty-three years of age Therefore, it should be emphasized that cardiac failure remains a threat to the patient with patent ductus arteriosus throughout his life, and that the likelihood of the development of this complication increases with the passage of time

As regards subacute bacterial endarteritis, there is a close parallelism between this lesion and subacute bacterial endocarditis of the type which not infrequently involves cardiac valves previously damaged by rheumatic fever In both instances the infecting organism most commonly is a Streptococcus viridans The source of the infection usually is some chronic focus such as the teeth, tonsils, prostate gland, etc Such foci apparently are relatively uncommon during childhood but develop during adolescence and especially during adult life The latter accounts for the relatively rare occurrence of subacute bacterial valvular and ductal infections during childhood and their much greater frequency at a later period In fact, such infections occur characteristically after puberty As in the case of cardiac failure, subacute bacterial endarteritis may appear at any time during the patient's life, and, accordingly, it must be considered a perpetual threat to life In the author's personal experience, such infections have been encountered as late as the seventh decade of life

An awareness on the part of the clinician that cardiac failure and subacute bacterial endarteritis constitute a perpetual threat to the life of the patient suffering from patent ductus arteriosus and that the likelihood of occurrence of both of these complications increases with the passage of time should lead to the decision to subject the patient to operation regardless of whether or not symptoms are present This dictum applies to all patients suffering from patent ductus arteriosus

A cogent argument in favor of operating at an early date, and preferably during childhood, is the universal opinion of experienced surgeons that operation is much simpler and safer in children than in adults The ductus of a child usually presents the physical characteristics of a normal blood vessel As such, it is resilient, readily compressible, and capable of being manipulated freely without fear of being torn or ruptured By contrast, the ductus of an adult frequently is atheromatous, sclerotic, and calcific When such a ductus is manipulated during operation, the danger of rupture is appreciably greater Furthermore, in adults the pulmonary artery is proportionately much larger in diameter than it is in children Dilatation of the pulmonary artery is invariably accompanied by considerable thinning of the wall of the vessel Not infrequently, the thin-walled, dilated pulmonary artery is adherent to the diseased friable ductus Under such circumstances, it is not difficult to appreciate the increased hazard of operation on adults and the desirability of proceeding with surgical treatment during childhood Finally, there are certain psychologic reasons for operating on patients with patent ductus while they are still quite young

In our present-day educational system, it is the rule to segregate all so-called "cardiac" children from their normal classmates This segregation is carried out regardless of the nature of the cardiac lesion or the degree of disability which it produces Thus, practically all patients with patent ductus arteriosus are so segregated Children in "cardiac" classes are not permitted to climb stairs or engage in competitive sports while in school While such a regime tends to reduce the incidence of cardiac failure by reducing the "cardiac load," it also tends to make the child very much aware of the fact that he is "different" from his normal classmates In some instances, this results in severe psychic trauma In other instances, it offers the child an excuse for assuming a tyrannical attitude toward the parents, especially if the latter are inclined to be oversolicitous The author has observed both types of reaction in children who have been "conditioned" by being placed in "cardiac" classes in school Suffice it to state that such an undesirable state of affairs can be prevented by subjecting children to operation prior to their entry into school

The author is of the opinion that all children, regardless of whether or not they present symptoms referable to ductal patency, should be subjected to operation The latter should preferably be performed before entry into school Unless the ductus is of unusually large caliber, such patients rarely present symptoms of circulatory insufficiency Furthermore, the incidence of subacute bacterial endarteritis is very low in such young individuals On the other hand, retardation of normal growth and physical development is not uncommon Operation in children of preschool age usually is quite simple and attended by insignificant morbidity and mortality in the hands of qualified surgeons In brief, the author considers it to be a highly desirable operation of "election."

Once the child enters school and is placed in a "cardiac" class, he becomes aware of the fact that he is different from his classmates As he grows older and tends to become physically more

REVASCULARIZATION OF THE HEART

CLAUDE S BECK, M D , Cleveland, Ohio

(From Western Reserve University and the University Hospitals, Cleveland, Ohio)

THIS work is based on approximately five thousand experimental operations carried out on the heart This work was begun in 1932 and with the exception of three war years has continued to the present time

In the ten-year period before the war three facts were brought out by experimental study One of these was the demonstration of a "trigger mechanism" in the heart If a portion of myocardium is made anoxic by ligation of the small coronary arteries supplying this area, it will be found that the anoxic area can destroy the coordinated heart beat and replace it by ventricular fibrillation Such relatively "dry areas" in the heart are responsible for most of the sudden deaths that occur in coronary artery disease A small amount of red blood delivered to one of these areas is important because it might prevent discharge of the trigger, fibrillation of the ventricles, and death

One purpose in this experimental work was to discover ways in which additional blood could be brought to the myocardium. The amount of blood need not be large, a relatively small amount would be beneficial How to get a supply of red blood was the problem Two methods were evolved One consisted of grafting adjacent tissues upon the surface of the heart with the expectation that arteries would grow across from graft to heart Every available structure was grafted upon the heart We obtained some nice specimens in which blood vessels of graft and blood vessels of heart were connected by anastomotic channels These communications did not always develop In a small percentage of experiments they could be demonstrated, in the remainder they could not

The second method of improving blood supply to the heart was the production of cross-channels between coronary arteries Coronary arteries are essentially end arteries They could be connected by the production of inflammation on the surface of the heart

These two methods were shown to be beneficial The test of benefit that we applied was ligation of descending ramus of left coronary artery at its origin in one step In the control group mortality was 70 per cent In the group that had these methods of revascularization applied to the heart the mortality was 38 per cent The destruction of heart muscle in the animals that survived ligation of the artery was less in the operated group than in the normal control group

Thirty-seven patients with severe coronary artery disease were operated upon using these methods It appeared that the results in these patients were beneficial

That briefly was the result of ten years of work The next development was to put red blood into the coronary sinus My associates and I have been developing this for the past three and one-half years I will give the results briefly The first problem concerned the technical job of putting red blood in the coronary sinus This was accomplished first by using the common carotid artery in dogs and later by placing a free graft of vein between aorta and coronary sinus (Fig 1)

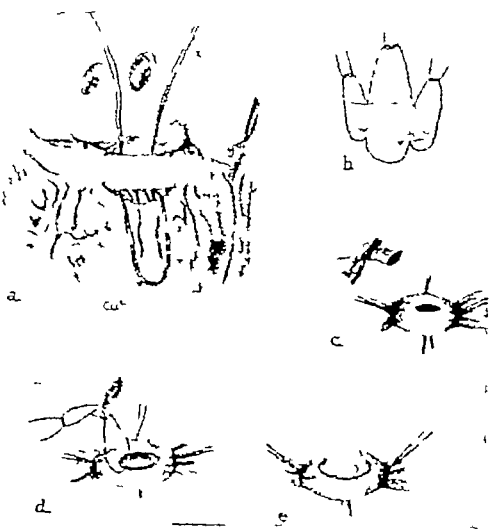

FIG 1 Anastomosis of left common carotid artery to coronary sinus in the dog (*a*) and (*b*) show method for isolation of segment of sinus so that it can be opened without hemorrhage The sinus is partially dissected free A carrier with two silk sutures is passed beneath the sinus at two points as indicated One piece of silk is cut A proximal and a distal ligature and a mattress suture are thereby provided. These are tied as in (*c*), and the sinus is opened. Four cardinal everting mattress sutures are placed between sinus and artery as shown in (*d*) The anastomosis is completed by a continuous everting suture (*e*) Trauma to sinus is minimal to prevent thrombosis [1]

The A Walter Suter Lectureship

Presented by invitation at the 143rd Annual Meeting of the Medical Society of the State of New York, Buffalo General Sessions May 6 1949

Supported by a research grant from the Division of Surgery U S Public Health Service

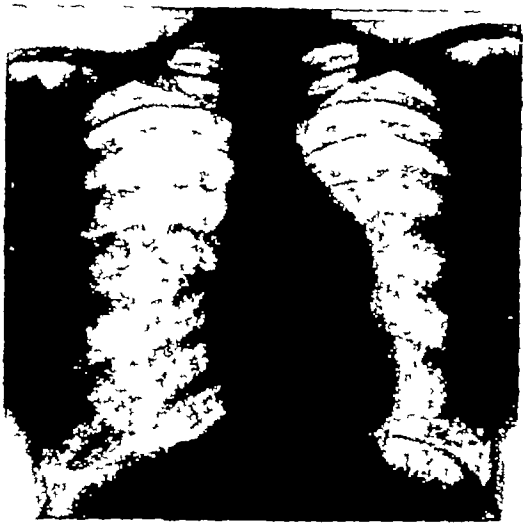

FIG 2 Film of chest one year after operation Note marked reduction in size of heart and persistence of prominence of pulmonary artery segment and bilateral pulmonary vascular congestion

left pleural cavity was entered through the third intercostal space after dividing the third and fourth costal cartilages The ductus, which was isolated without difficulty, was found to measure 1 cm in length and 2 cm in diameter The pulmonary artery was markedly dilated, measuring approximately 5 cm. in diameter The aorta was of normal caliber The ductus was doubly ligated with heavy silk After the latter had been accomplished, the blood pressure rose from 120/50 to 140/90, the continuous coarse thrill which could be readily palpated in the pulmonary artery disappeared The thoracic wound was closed in layers after aspirating the air in the pleura with a catheter

The postoperative course was uneventful, the wound healing by primary union On regaining consciousness, the patient volunteered the information that the "buzzing noise" which she had always noted in her chest had disappeared She was discharged from the hospital on the seventh postoperative day with the wound firmly healed At that time, the blood pressure was 116/88, and the patient was in excellent general physical condition She has been kept under observation since then (a period of one year) and has remained in excellent health She now is entirely free of symptoms and, for the first time in her life, indulges in any desired type of physical activity On physical examination, a very faint short systolic murmur is audible over the third left intercostal space at the previous site of the continuous "machinery" murmur An x-ray film of the chest, taken on May 2, 1949, revealed marked reduction in the size of the heart (Fig 2) The pulmonary artery segment remains prominent, however, and bilateral pulmonary vascular congestion is still noted. (These findings are in keeping with those which we have noted on many occasions among adults) At the present writing the patient is four months pregnant and feels very well

Comment

The foregoing case presents many features which the author has observed in other cases of patent ductus arteriosus among adults, notably the occurrence of subacute bacterial endarteritis and circulatory insufficiency The patient's small stature may be attributed to the presence of the patent ductus At operation, the ductus was found to be of large caliber and, had it not been for the fact that the patient had voluntarily restricted her physical activity throughout her life, cardiac failure would almost certainly have appeared at a much earlier age However, despite the fact that she led a sedentary life, circulatory insufficiency eventually did occur as the result of continued cardiac strain Fortunately, when subacute Streptococcus viridans endarteritis developed, the infection could be brought under control readily with penicillin therapy However, it should be emphasized that there are not a few organisms which are insensitive to all of the antibiotics which presently are available This fact constitutes a particularly forceful argument in favor of operation in all cases of patent ductus before infection develops, in the author's experience, operation has served to protect the patient against the development or recurrence of infection

Summary and Conclusions

Surgical treatment of patent ductus arteriosus is definitive inasmuch as it corrects the existing anatomic abnormality

The complications of the condition are failure of normal growth and physical development, circulatory insufficiency, and subacute bacterial endarteritis

All of the foregoing complications can be prevented or corrected by operation

In the hands of experienced surgeons, the morbidity and mortality of operation is negligible

Operation is recommended in all cases of patent ductus arteriosus, regardless of whether or not the patient presents symptoms

The optimum time at which operation should be performed is before a child enters school (usually between the ages of three and five)

All adults suffering from patent ductus arteriosus should be subjected to operation without delay because of the almost inevitable development of circulatory insufficiency if unoperated and the high incidence of subacute bacterial endarteritis

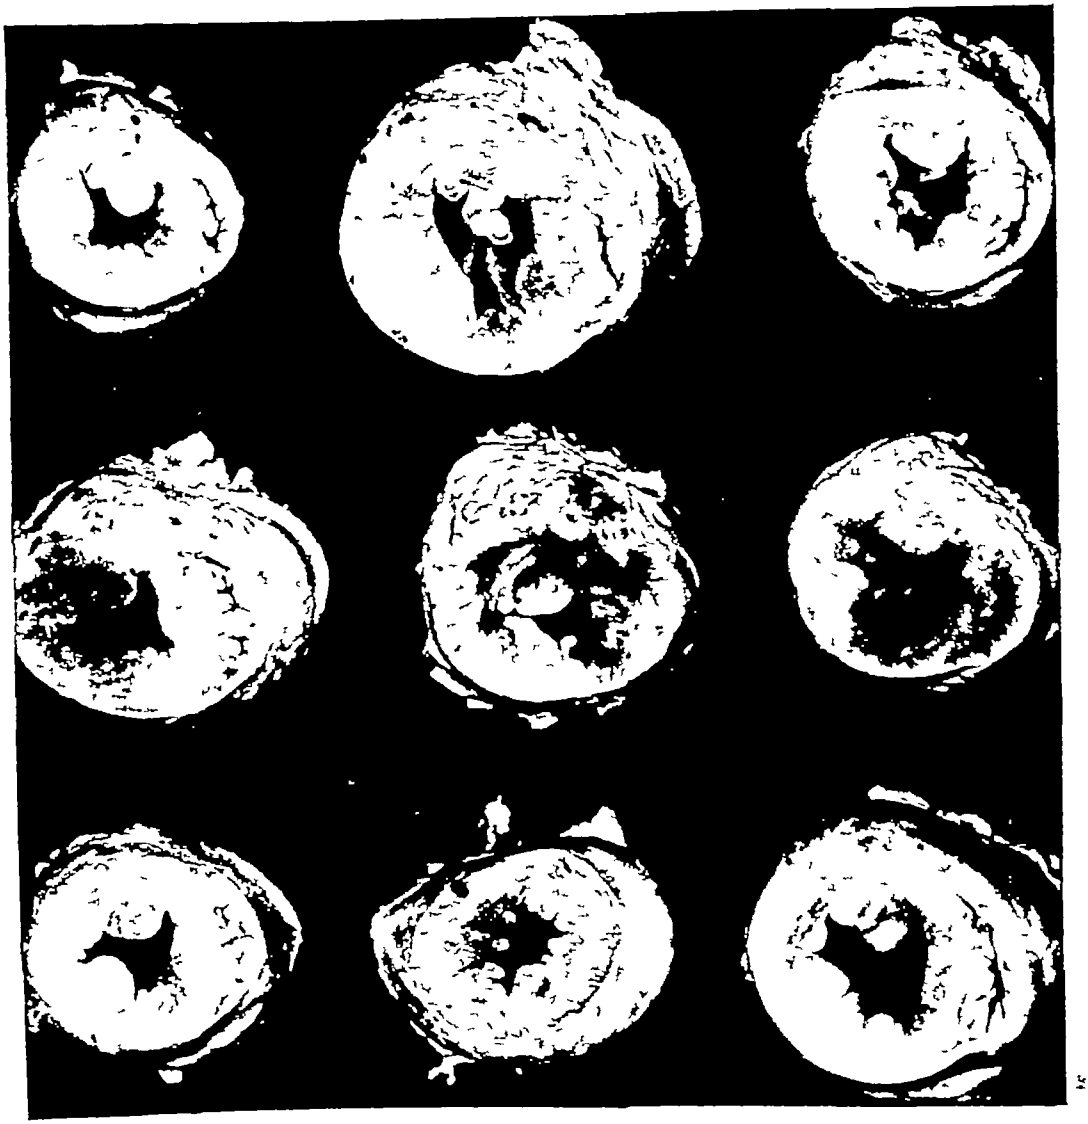

FIG 4. Infarcts in group with anastomosis between artery and coronary sinus The descending ramus of the left coronary artery was ligated in a group of ten dogs. There were no immediate deaths after this ligation In four specimens there was no infarct In the other specimens destruction was minimal and appeared in scattered areas In no specimen was extensive destruction of myocardium found as occurred in each of the control group [2]

problem is application to patients in such a way that the graft will remain patent and the myocardium will be able to take the increased load of blood Both of these problems are being solved

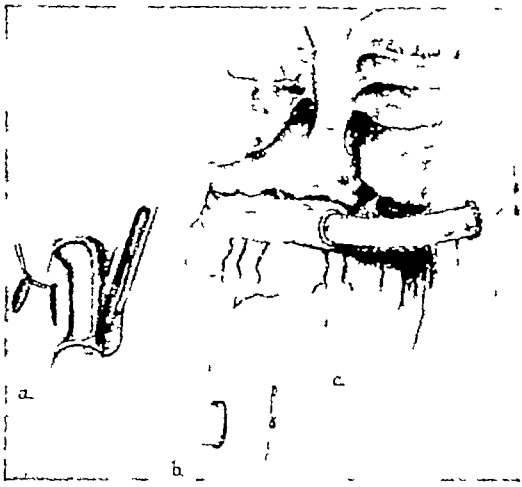

FIG 2 *Free graft of vein between aorta and coronary sinus of the dog* The aorta is dissected free for a distance of about 3 cm. Two intercostal arteries are cut The special clamp is placed on aorta as in (*a*) allowing some blood to pass the clamp The aorta is opened by incision about 5 mm in length An everting mattress suture is placed between graft and aorta at each end of this incision Anastomosis is completed by a continuous everting suture as in (*b*), (*c*) shows the complete operation [1]

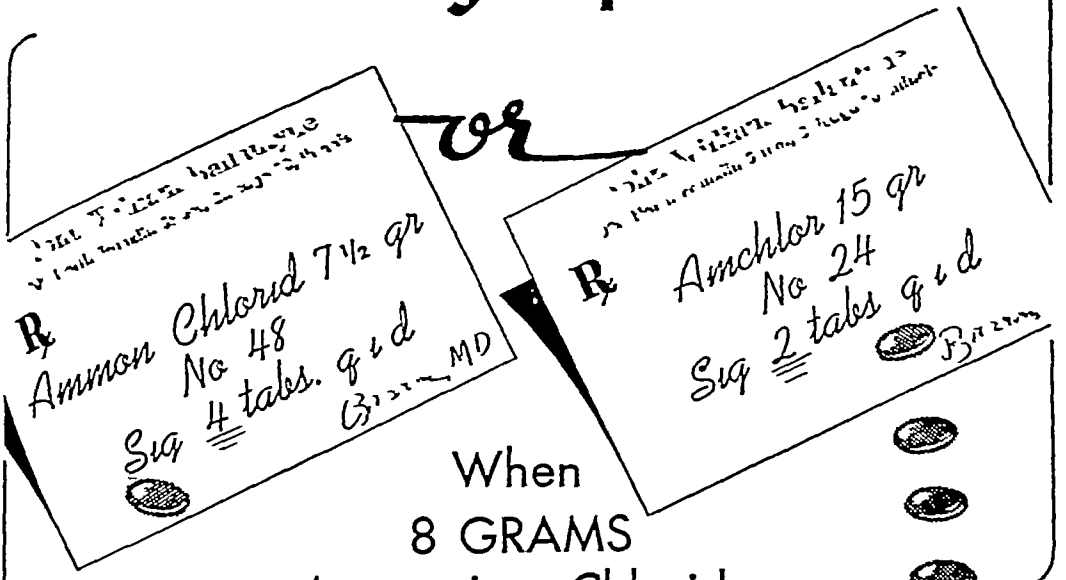
This operation was done successfully Red blood was directed into the coronary vein and into the myocardium All the technical problems have not yet been completely overcome, but we have recently achieved almost routine success in experimental animals I need scarcely refer to the technical problems and difficulties of this development It seems to me that nowhere in the history of surgery has a technical development required so much experiment

The next subject concerns test of benefit after you get red blood in the sinus How much good does this do? Here is the most important consideration of our work When we tied off the descending ramus of the left coronary artery at its origin in one step, we obtained an important difference in mortality in dogs with arterial blood in the sinus as compared to normal dogs. In dogs with a new artery in the heart there were no immediate deaths after ligation of the test artery, there was one death at the end of eight days, one at the end of thirteen days, these dogs almost got by, eight lived In normal control dogs only three out of ten lived The amount of destruction of myocardium was definitely less than in the control group Any normal heart that survives ligation of the test artery has a large infarct In the grafted hearts there was no infarct in half the specimens, and in no specimen was the infarct as large as in control specimens (Figs 2 and 3) Expressed in other words, we found that, after arterial blood was delivered to the coronary sinus, it was possible to ligate a major coronary artery with little or no mortality and with little or no destruction of heart muscle It may be difficult at this time to appreciate the significance of this observation



The next problem is to apply this development to human patients So far we have not made significant progress As of May 1, 1949, we have operated on only five patients Two are living I feel that within the immediate future our problems will be straightened out so that we can go ahead with patients

Finally, I should like to express myself on one point I am not worried or concerned about the beneficial result of the operation Our experiments have answered that problem before we get the answer on patients, and I am convinced that the operation will be highly beneficial Our

FIG 3 Infarcts in the control group The descending ramus of the left coronary artery was ligated in a group of ten dogs. Only three animals survived this ligation and each of these specimens showed a large infarct [2] Compare with Fig 4

NECROLOGY

Elias William Abramowitz, M D , sixty-three, died June 13 at his home in New York City after a long illness Born in Jassy, Rumania, he was brought to New York when a child and received his medical degree from University and Bellevue Medical College in 1907 After interning at Mount Sinai Hospital and serving as assistant house surgeon at the New York Lying-In Hospital, Dr Abramowitz began general practice in New York City

In 1911 Dr Abramowitz began the study of dermatology at Mount Sinai, and in 1914 joined the staff at Vanderbilt Clinic, Presbyterian Hospital, where he was attending dermatologist when he left in 1926 Since 1927 he had been associated with the New York Post-Graduate Medical School, where he was clinical professor of dermatology and syphilology

During World War I Dr Abramowitz was a member of the Council of National Defense and an instructor for an intensive course in dermatology given at Columbia University under Army and Navy auspices He also worked in the venereal disease clinic of the City Health Department under Federal supervision During World War II, he was a selective service dermatologist at Gouverneur Hospital

Dr Abramowitz was director of the dermatology and syphilology staff at Gouverneur Hospital, attending dermatologist and syphilologist for the skin and cancer unit of the Post-Graduate outpatient department, and chief of the dermatology and syphilology staffs at Jewish Memorial, Maimonides, and Liberty Hospitals

A Diplomate of the American Board of Dermatology and Syphilology, Dr Abramowitz was a member of the American Academy of Dermatology and Syphilology, the New York Academy of Medicine, the Manhattan Dermatological Society, the Brooklyn Dermatological Society, the New York State and County Medical Societies, and the American Medical Association

Franklin William Barrows, M D , who practiced in New York State before his retirement several years ago, died on May 25 at his home in Dumont, New Jersey He was eighty-six Dr Barrows was graduated from the University of Buffalo School of Medicine in 1893 and practiced in Buffalo until 1918, when he joined the New York State Department of Education In 1929 he moved to New Rochelle, where he was school medical adviser until 1934, when he retired. Dr Barrows was a member of the Medical Society of the State of New York and the American Medical Association

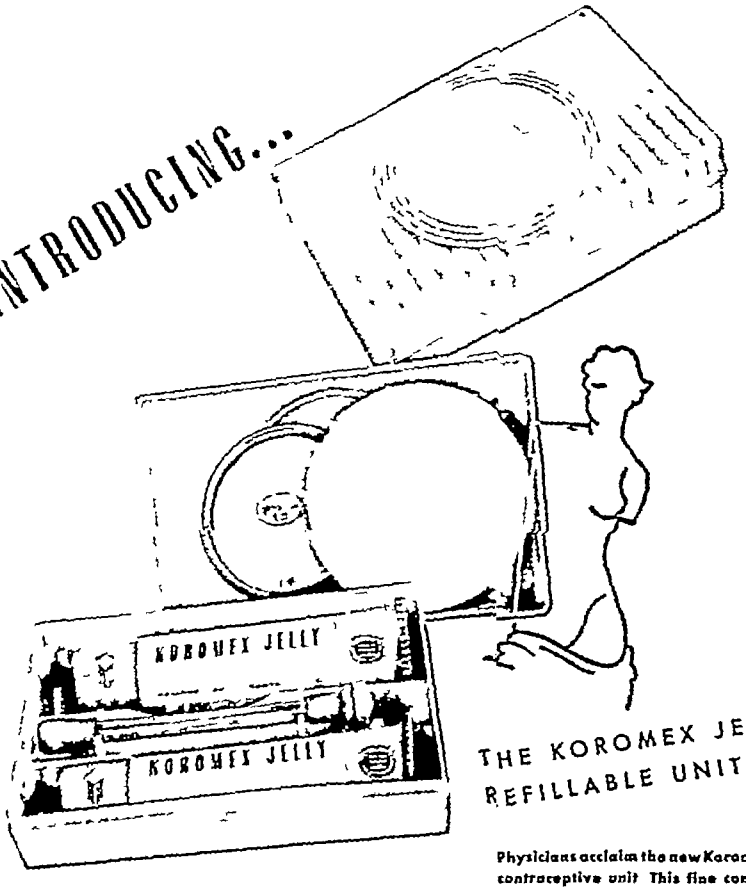
Robert Lander Bartlett, M D , seventy-four, former superintendent of the Oneida County Hospital, died on May 25 in Warm Springs, Virginia, where he had lived since his retirement in June, 1947 Dr Bartlett was graduated from the Tufts Medical School, Boston, Massachusetts, in 1898, and from the University and Bellevue Medical College in 1901

Following his internship at the Riverside Hospital, New York City, Dr Bartlett joined the Army Medical Corps and served at Chickamauga, Anniston, Alabama, and in Cuba. Following his postgraduate studies he went to the Philippines, where he was medical inspector with the Insular Board of Health. Dr Bartlett later served in Panama, under the direction of Colonel Gorgas, and for two years was in charge of Mira Flores Hospital. He supervised the sanitation program in the Republic of Panama to prevent the introduction of disease into the Canal Zone and was then transferred to the Ancon Hospital

Dr Bartlett next went to Brazil to take charge of the medical and hospital work of an English corporation engaged in improving the harbor of Para on the Amazon River After two years there, he went to Germany for further study and then returned to open a practice in New York City In 1913 he assumed the position as superintendent of the Oneida County Hospital in Rome, which he held for thirty-four years until his retirement

Dr Bartlett was a member of the Oneida County and New York State Medical Societies and the American Medical Association

Albert Jay Colton, M D , of Buffalo, died on June 19 at the age of eighty-five He received his medical degree in 1890 from the University of Niagara Medical Department Dr Colton was the inventor of the Colton system, a card-index designed to simplify physicians' bookkeeping and case-history recording He had been a practicing physician in Buffalo for thirty-three years until his retirement eight years ago He was a member of the Buffalo Academy of Medicine, the Erie County and New York State Medical Societies, and the American Medical Association



Avac Cutujian, M D , eighty-eight, died on May 16 in Frederick, Maryland, where he had lived since his retirement three years ago from his New York City practice A native of Marash, Turkey, Dr Cutujian received his medical degree from the Long Island College Hospital in 1893 He practiced in New York City for more than fifty years, until his retirement

Alexander Goldman, M.D , founder and first president of the Bronx Hospital, died on June 15 at his home in the Bronx at the age of seventy-seven Dr Goldman, who was born in Moscow, Russia, came to the United States in 1890 after being graduated from the Sorbonne University in Paris He received his medical degree from the College of Physicians and Surgeons, Columbia University, in 1906, and the following year was associated with the late Alexander Lambert, M D , in establishing the first gastroenterologic clinic at the Vanderbilt Clinic of the Presbyterian Hospital

Dr Goldman was a leader in the movement to build the Bronx Hospital He served as its president for ten years and was head of its medical board until five years ago, when he was elected president emeritus of the board Dr Goldman was chief in endocrinology and consultant in internal medicine at the Bronx Hospital, and consultant in gastroenterology at the Morrisania Hospital. He was a member of the Bronx County and New York State

INTRODUCING...

THE KOROMEX JELLY REFILLABLE UNIT

Physicians acclaim the new Koromex all inclusive contraceptive unit This fine container is ivory-colored plastic, permanent dust-proof attractive for home use and ideal for traveling it contains two regular size tubes of Koromex Jelly which rest in individual compartments a Koromex Diaphragm stored in the ingeniously constructed cover compartment and a Koromex Measured Dose Plunger Applicator that rests securely on its own rack.

Where pregnancy is contra indicated recommend the complete Koromex Jelly Refillable Unit to your discriminating women patients.

For those of your patients who require a slightly less lubricating but equally effective spermicidal preparation a similar companion package containing two tubes of Koromex Cream instead of Koromex Jelly is also available

ACTIVE INGREDIENTS BORIC ACID 2 0% OXYQUINOL H BENZOATE 0 02% AND PHENYLMERCURIC ACETATE 0 02 % IN SUITABLE JELLY OR CREAM BASES

Medical Societies and the American Medical Association

Albert Michael Healey, M D, of the Bronx, died on June 12 at the age of sixty-seven A graduate of the University and Bellevue Medical College in 1907, Dr Healey had practiced for forty years in the Inwood district of Manhattan until he retired five years ago He was a member of the Bronx County and New York State Medical Societies and the American Medical Association

Charles Johnstone Imperatori, M D, seventy-one, formerly of New York City, died on June 15 at his home in Essex Dr Imperatori, who represented the seventh generation of physicians in his family, received his medical degree from the University and Bellevue Medical College in 1899 and served for a year with the United States Public Health Service in the Panama Canal Zone Following this, he opened his ear, nose, and throat practice in New York City

Dr Imperatori was professor of laryngology at the New York Post-Graduate Medical School and Hospital from 1922 to 1928, visiting surgeon at Bellevue Hospital from 1917 to 1921 and from 1930 to 1935, and clinical professor of otolaryngology at New York University Medical School from 1932 to 1935 He was consulting bronchoscopist at the Manhattan Eye, Ear and Throat Hospital and consulting laryngologist at the Harlem, Flower and Fifth Avenue, and Correction Hospitals, in New York City, and the Nyack Hospital

During World War I, Dr Imperatori served in France as a lieutenant colonel in command of the 309th Medical Regiment of the 84th Division, A.E.F For his services France decorated him with the Medaille D'Honneur Des Epidemies In World War II he was a member of the Division of Medical Sciences of the National Research Council

Former president of the American Laryngological Association, the American Bronchoscopic Society, and the New York Laryngological Society, Dr Imperatori was a Fellow of the American College of Surgeons and the American Academy of Ophthalmology and Otolaryngology, a Diplomate of the American Board of Otolaryngology, and a member of the New York Academy of Medicine, the New York County and State Medical Societies, and the American Medical Association

Anna W Locke-Henry, M D, New York City, died on February 14 at the age of eighty-one Dr Locke-Henry received her medical degree from the University of Michigan Medical School in 1897

Charles Jacob Mark, M D, sixty-eight, of New York City, died on March 23 A graduate of the Long Island College Hospital in 1906, Dr Mark was assistant attending dermatologist at Gouverneur Hospital in New York City

Walton Martin, M D, New York City, died on June 18 of a cerebral hemorrhage at his summer home in Cornwall, Connecticut He was eighty years old A graduate of the College of Physicians and Surgeons, Columbia University, in 1892, Dr Martin interned at Roosevelt Hospital and then became a member of the staff of St Luke's Hospital, on which he remained until his death

During World War I, Dr Martin installed the Ambulance B section at the American Hospital in Neuilly, France He was the author of many books on surgery, and did the revision of Green's *Pathology* Dr Martin attended the late President Theodore Roosevelt during his last illness in 1918 and also treated the late Dr Nicholas Murray Butler, former president of Columbia University

A Fellow of the American College of Surgeons, Dr Martin was a member of the American Society of Thoracic Surgery, the American Surgical Association, the New York Academy of Medicine, the New York Surgical Society, the New York County and State Medical Societies, and the American Medical Association

Earl H Mayne, M D, eighty-two, of Brooklyn, died on June 9 in Newport, Vermont, of a heart attack He received his medical degree in 1893 from the Bellevue Hospital Medical College and began his practice in Brooklyn, where he continued for more than fifty years, until 1948 Dr Mayne was one of the founders of the Bay Ridge Hospital and served as president of its board of directors He was a former president of the Bay Ridge Medical Society and a Fellow of the American College of Surgeons In 1944 he founded the Mayne Educational Fund to aid worthy young people acquire educational advantages Dr Mayne was a member of the Kings County and New York State Medical Societies and the American Medical Association

Morris C Smitkoff, M D, of Brooklyn, died on June 1 at the age of forty-four Dr Smitkoff was graduated from the Cornell University Medical College in 1931 and was assistant attending physician in arthritis at the Jewish Hospital of Brooklyn He was a member of the New York Rheumatism Association, the American Rheumatism Association, the Kings County and New York State Medical Societies, and the American Medical Association

Max Wolper, M.D, a New York City physician for fifty-nine years, died on June 22 at his home after an illness of two months He was eighty-seven A native of Berlin, Germany, Dr Wolper was graduated magna cum laude from the University of Berlin in 1888, and came to this country and set up his office in East Broadway, New York City, the following year

Dr Wolper was well known many years ago as a horse-and-buggy doctor on the Lower East Side During his career he delivered approximately 10,000 babies, and received permission from the police to equip his buggy with a fire gong to facilitate getting through crowded streets in response to hurry calls He retired from practice a year ago, when his health began to fail

Dr Wolper was a member of the New York County and State Medical Societies and the American Medical Association

A REALLY DELICIOUS STOUT

. . . WITH SPECIAL QUALITIES

★ Since the introduction of MACKESON'S MILK STOUT to America, this internationally-known brew has met with the most favorable acceptance by leading members of the medical profession ★ Brewed from the finest British malt, MACKESON'S MILK STOUT is a product of the highest grade in respect to purity and body It differs from ordinary stout in that it contains the carbohydrates of the purest dairy milk which increase its protein content and nutritive value – and to which its distinctive mellowness and very palatable flavor are due ★ These special qualities of MACKESON'S MILK STOUT have long been recognized as beneficial in all cases where a stout may be recommended on medical grounds

WOMEN DOCTORS FARING WELL

Though still a medical minority, U S women physicians today occupy an important niche in the profession Here are a few facts on their status garnered from a nation-wide survey published in the June issue of *Medical Economics*

Women practitioners net an average annual income of $7,929 (male doctors average $11,036) They devote nine hours a day to their medical practice (one hour less than men), spend an equivalent of 41 days a year in postgraduate study (eight days more than men) They allow 25 days a year for vacations (to men's 16 days) Only 12 per cent are in full specialty practice (as against 31 per cent of men)

USED BY PHYSICIANS FOR 14 YEARS*

Ray-Formosil for intramuscular injection is a clinically proved, effective treatment for Arthritis and Rheumatism. It is a non-toxic, sterile, buffered solution containing in each cc.

SUMMARY OF MINUTES OF THE COUNCIL OF THE MEDICAL SOCIETY OF THE STATE OF NEW YORK

AT ITS meeting immediately following adjournment of the House of Delegates on May 4, 1949, the Council considered the following matters, taking action as indicated

Secretary's Report

Remission of Assessments —Remission of annual assessments was voted on account of service with the armed forces for one member for each of the following years 1942, 1943, 1944, 1945, 1946, 1947, and 1948 Annual and war memorial assessments for three members were remitted on account of illness Two assessments were refunded due to illness

Nomination to Associate Fellowship in the American Medical Association was approved for Dr Charles Rich

Treasurer's Report was accepted

Executive Officer s Report

Dr Hannon stated that he was about to make arrangements for the meetings of executive committees of the District Branches, and that he would appreciate suggestions regarding matters that should be considered at these meetings

New Business

Dr Anderton read, for information, a telegram sent by order of the House of Delegates to Mrs John L O'Brien, expressing sympathy at the death of her husband, Dr John L O'Brien

The President *was voted* power to appoint the Convention Committee and the Arrangements Committee for the 1950 Annual Meeting *It was also voted* that the Convention Committee should select the place and date for the meeting

The President requested suggestions of names of members for committees

There was discussion about submitting desired changes in the new Workmen's Compensation Fee Schedule to Miss Donlon before its final printing

The President requested chairmen of committees to send their reports to the Secretary sufficiently in advance so as to have them distributed with the agenda of Council meetings

---

CURARE PREPARATION RELIEVES SYMPTOMS OF ARTHRITIS

A preparation of a South American arrow poison, curare, is bringing relief to persons suffering from the painful chronic disease, rheumatoid spondylitis, a form of arthritis that affects the spine

Use of the preparation, *d*-tubocurarine suspended in oil and wax, is reported by Bernard M Narcross, M D , and Harold M Robins, M.D , of the University of Buffalo Medical School, Buffalo, in the May 28 issue of the *Journal of the American Medical Association*

In six cases in which the doctors administered the preparation, after other treatment usually prescribed for the disease had failed to produce improvement, the patients were relieved of pain, their muscles were relaxed, deformity of the spine was corrected, and they were able to take more exercise

---

SPECIALISTS' EARNINGS TOP G.P 'S BY 50 PER CENT

Medicine's specialists earn half again as much as the average net income of general practitioners, reports *Medical Economics*, national business magazine for physicians

"No specialty in 1947 averaged less than $19,000 gross or about $12,000 net," according to figures from a nation-wide survey published in its May issue ' Thus the lowest-paying specialty netted its average practitioner about $2,500 more than the average net of G P 's"

Average net incomes of independent doctors in the seven top-paying specialties in 1947 are reported as follows roentgenology and radiology, $20,319, obstetrics and gynecology, $17,320, eye, ear, nose, and throat, $16,068, surgery, $16,011, psychiatry, $14,774, neuropsychiatry, $14,371, and ophthalmology, $14,099

"The disparity between the incomes of specialists and G.P 's," the magazine concludes, "is increased by the fact that the G.P spends 22 per cent more time practicing and sees almost 23 per cent more patients than the full specialist does."

Histamine Iontophoresis

To the Editor

Histamine iontophoresis as a new therapeutic method was first introduced by Deutsch in 1931 He used it successfully in the treatment of such conditions as muscular rheumatism and fibrositis, assuming that local and regional hyperemia is responsible for the therapeutic results In 1934 I described a method of craniocerebral iontophoresis applied to the forehead and nape of the neck Here, too, results were encouraging Moderate and severe attacks of migraine as well as hypertensive and arteriosclerotic headaches respond immediately to the treatment At the same time there is a marked fall of systolic blood pressure in hypertensive patients These observations encouraged further therapeutic attempts in various organic diseases of the brain, such as multiple sclerosis, Parkinsonism, chorea, and other encephalitic disorders Two of three multiple sclerosis cases responded with immediate relief In one patient the existing nystagmus and ataxia subsided within an hour following treatment In another case, blurred vision due to retrobulbar neuritis cleared up for a period of days I recorded these results as striking indications of the efficacy of the method but emphasized their transient nature

Comparing the technic of craniocerebral ionization with the method described by Abramson (New York State Journal of Medicine, May 15, 1949, page 1151), it is interesting to note that the concentration of histamine solution used in my method (1 5,000) is only a fraction of the one applied by Abramson I have also found that the described cerebral (or cerebrovascular) effects were much more marked when the treatment was applied to other parts of the body This suggests that, besides the systemic reactions due to the introduction of histamine into skin and general circulation, a local and regional effect as assumed by Deutsch must be involved This is also borne out by the fact that, on using the so-called urticariogenic effect of dionine (diethylhydromorphine) instead of histamine under the positive pole, identical clinical and vasodepressive reactions can be observed

These observations show that whatever be the ultimate verdict regarding the therapeutic potentialities of histamine ionization, further clarification of its modus operandi is desirable

Jan Ehrenwald, M D
66 East 78th Street
New York City

June 1, 1949

Reply by Dr Abramson

To the Editor

I was very glad to have the privilege of seeing Dr Ehrenwald's letter and should like to take up its contents point by point

I was fully aware that Deutsch used histamine iontophoresis for the treatment of arthritis However, whether he used it successfully or not is another matter We all know that electrophoresis or iontophoresis is used for many diseases However, the therapeutic claims by those who have used the electrophoretic method far outweigh the scientific evidence which has been accumulated to explain the modus operandi Dr Ehrenwald points out that in 1934 he used a method of craniocerebral iontophoresis applied to the forehead and nape of the neck It is my impression, after listening to those who use this technic, that they believe that the electric current and the drug actually permeates all the tissues between the electrodes to produce its therapeutic effect I do not know if Dr Ehrenwald believes this or not, but this much is certain, that the basic law of electricity, namely Ohm's law, is followed, and I should be very much surprised if the paths of the current and therefore the movement of the drug carries out the desire of the physician to apply the drug directly to the brain or nervous system itself Indeed, if the electrode is applied to the skin, the skin blood vessels will absorb the fluid on the nape of the neck or the forehead or anywhere else on the body It is quite true that there will be a difference in the rate of absorption of the drug with different areas of vascularity and lymphatic supply, but misconceptions of this type alluded to by Dr Ehrenwald have been described in detail in my two books, *Electrokinetic Phenomena* (Reinhold Publishing Company, New York City) and *Electrophoresis of Proteins*, with Moyer and Gorin (Reinhold Publishing Company, New York City, 1942)

Apparently, Dr Ehrenwald found that in two of three multiple sclerosis cases immediate relief was obtained As my rather extensive work and that of Jonez on the subject discloses, such spectacular results are not always to be encountered The psychologic effects of the therapy, especially if an electrode is applied to the skull, are too obvious to be mentioned further

The cerebral or cerebrovascular effects obtained by Dr Ehrenwald must be ascribed to absorption through the skin from the electrode and not on the cerebrum itself Any effect on the cerebrum must be of a minor order or magnitude Finally, I quite agree with Dr Ehrenwald that the modus operandi of the effect of histamine is desirable, but I do not feel that the modus operandi should be determined by therapeutic claims which are apt to dispute the elementary laws of electricity and to neglect the basic principles of psychodynamics in therapy

Harold A Abramson, M D

DELICIOUS *Candy*

FOR MANY USES IN THERAPEUTICS

Candy, widely used empirically in medical practice by the ancient physicians, is employed therapeutically today in its many forms on a sound rational basis

Hard dextrose candies, providing concentrated carbohydrate food energy, are particularly useful as a source of carbohydrate in the treatment of liver and other diseases Medicated candy is widely employed in oral and respiratory infections, and is especially applicable for administering distasteful drugs to both children and adults Candies, appealing in taste, cheer the convalescent patient, thus encourage a more favorable outlook by a direct psychosomatic approach

Many candies also contain milk, cream, butter, eggs, nuts and peanuts—all valuable food ingredients Such candies, to the extent they provide these component foods, supply biologically desirable protein, vitamins and minerals

Candy in moderation is wholesome food in the adequate diet of both children and adults

THE NUTRITIONAL PLATFORM OF CANDY

1 Candies in general supply high caloric value in small bulk.

2 Sugar supplied by candy requires *little* digestive effort to yield available energy

3 Those candies, in the manufacture of which milk, butter, eggs, fruits, nuts, or peanuts are used, *to this extent* also—

(a) provide biologically adequate proteins and fats rich in the unsaturated fatty acids;

(b) present appreciable amounts of the important minerals calcium, phosphorus, and iron;

(c) contribute the niacin, and the small amounts of thiamine and riboflavin, contained in these ingredients.

4. Candies are of high satiety value; eaten after meals, they contribute to the sense of satisfaction and well-being a meal should bring; eaten in moderation between meals they stave off hunger

5 Candy is more than a mere source of nutriment—it is a morale builder a contribution to the joy of living

6 Candy is unique among all foods in that it shows relatively less tendency to undergo spoilage, chemical or bacterial.

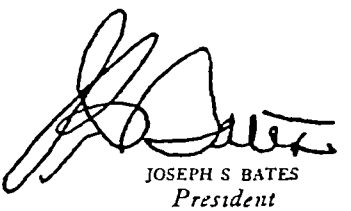
February, 1949	up to 30%
June, 1949	up to 35%

*Ciba brand of testosterone propionate U S P

The Story

Behind Perandren Price Reductions



AGAIN in June, Ciba reduced the prices of Perandren by amounts up to 35 per cent This was the second such reduction in 1949

Ciba introduced Perandren in 1936 as the result of the successful synthesis of testosterone propionate after years of exhaustive research Ever since, this product has been subjected to a policy of investigation of all phases of its clinical application as well as the efficiency of its manufacture This policy has been supported by large investments of money and research effort

One result of this broad program has been the data and conservative advice which Ciba has been able to place at the disposal of the medical profession Another result has been a gradual increase in manufacturing efficiency with its concomitant savings in cost These savings, together with those which have come from the steadily increasing demand for Perandren, have been passed on in large part to the user, in conformity with what Ciba conceives to be its responsibility to the medical profession and the public

Ciba was the first to bring about drastic reductions in the price of testosterone propionate Now Perandren is benefiting many times the original number of patients, and, with the announcement of another price reduction, Perandren is less than 20% of its original price

This is concrete evidence of our adherence to the Ciba policy of sharing economies from technological advances with those who enjoy the therapeutic benefits of Perandren the Ciba brand of testosterone propionate

DELICIOUS *Candy*

FOR MAN
THERAP

Candy, widely used empirically in t
the ancient physicians, is employ
today in its many forms on a sound

Hard dextrose candies, providing con
hydrate food energy, are particularly us
of carbohydrate in the treatment of li
diseases Medicated candy is widely em
and respiratory infections, and is especia
for administering distasteful drugs to b
and adults Candies, appealing in taste, che
valescent patient, thus encourage a more
outlook by a direct psychosomatic approach

Many candies also contain milk, cream, butt
nuts and peanuts—all valuable food ingredient
candies, to the extent they provide these com
foods, supply biologically desirable protein, vit
and minerals

Candy in moderation is wholesome food in the
quate diet of both children and adults

THE NUTRITIONAL PLATFORM OF CANDY

1 Candies in general supply high caloric value in small bulk.

2 Sugar supplied by candy requires little diges tive effort to yield available energy

3 Those candies, in the manufacture of which milk, butter, eggs fruits nuts, or peanuts are used to this extent also—

(a) provide biologically adequate proteins and fats rich in the unsaturated fatty acids;

(b) present appreciable amounts of the impor tant minerals calcium, phosphorus, and iron;

(c) contribute the niacin, and the small amounts of thiamine and riboflavin, contained in these ingredients

4 Candies are of high satiety value; eaten after meals, they contribute to the sense of satisfaction and well-being a meal should bring; eaten in moderation between meals, they stave off hunger

5 Candy is more than a mere source of nutri ment—it is a morale builder a contribution to the joy of living.

6 Candy is unique among all foods in that it shows relatively less tendency to undergo spoil age chemical or bacterial.

This Platform is Acceptable for Advertising in the Publications of the American Medical Association

BACKGROUND

The use of cow's milk, water and carbohydrate mixtures represents the one system of

infant feeding that consistently, for over three decades, has received universal pediatric

recognition No carbohydrate employed in this system of infant feeding enjoys so rich and enduring a background of authoritative clinical experience as Dextri Maltose.

METANDREN LINGUETS

LOW-COST MALE HORMONE THERAPY

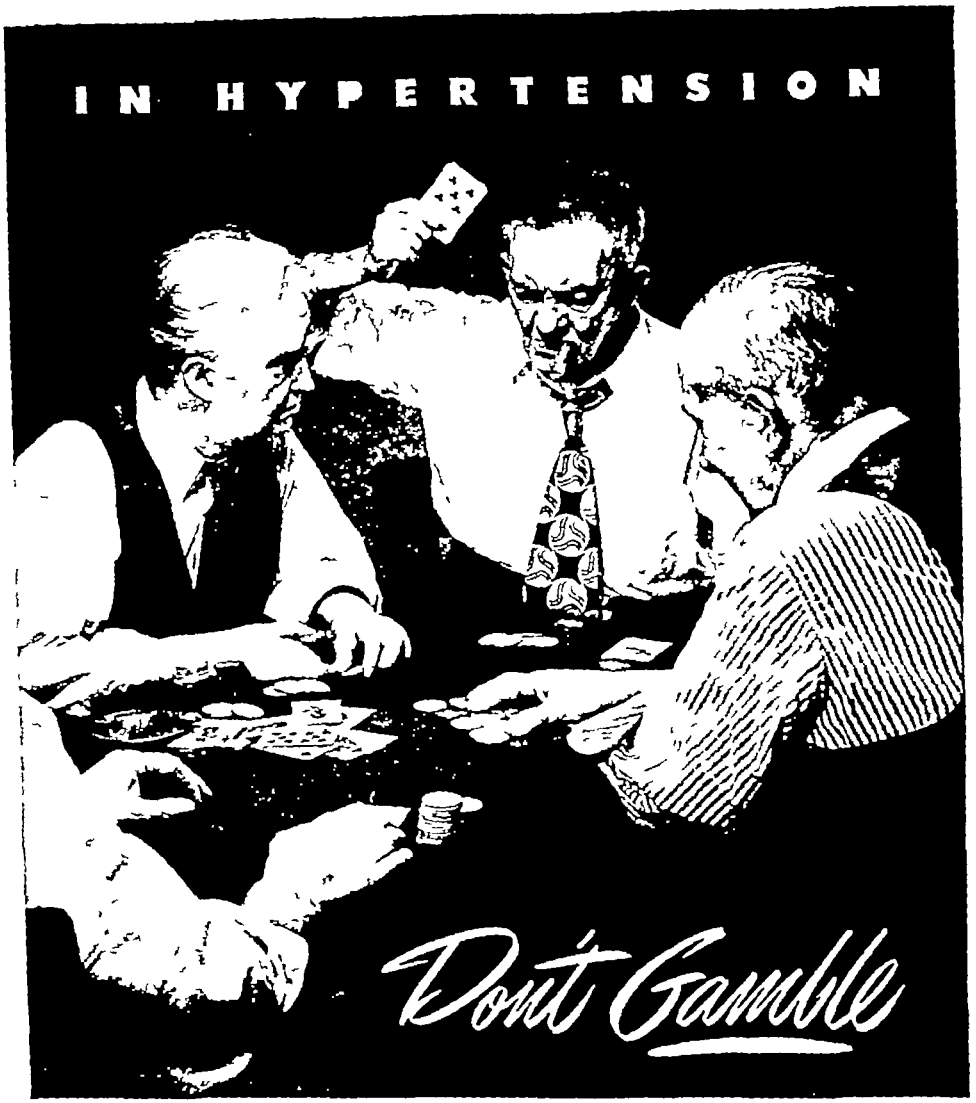
. . . with nearly twice the potency of ingested tablets

Metandren Linguets contain methyltestosterone for sublingual or buccal administration

The superiority of Metandren Linguets over other androgens by this route may be partly attributed to the fact that only methyltestosterone is effective orally In contrast, when free testosterone or testosterone propionate is given sublingually, that portion unavoidably swallowed is almost completely destroyed

Metandren Linguets of methyltestosterone are the 'most economical and also efficient way of administering testosterone," according to Lisser [1] Tyler finds that 140 mg of methyltestosterone weekly in the form of Linguets is equivalent to an ingested dosage of approximately 210 mg or to an injected dosage of 75 mg of testosterone propionate

PERANDREN
is the pioneer brand of testosterone propionate, the most potent injectable androgen



Adult maintenance dosage is from one to three 5 mg Linguets daily Most children need only one-half to one 5 mg Linguet daily Literature on request

THE CLIFTON SPRINGS SANITARIUM AND CLINIC

CLIFTON SPRINGS, NEW YORK

Hospital and Clinic Building

Sanitarium Main Building

THE CLINIC

Medical sections for the care of metabolic and cardiovascular diseases, arthritic, psychoneuroses, gastroenterology, pediatrics and hematology, as well as general diagnosis are available Surgical sections are available for general surgery and the various surgical specialties Laboratory sections are maintained for radiology and pathology

The clinic is general and maintains competent medical, surgical and laboratory staffs All types of general medical and surgical cases are received for diagnosis and treatment Recognized forms of physiotherapy are provided There is an excellent dietetic service No cases of active pulmonary tuberculosis, contagious disease, epilepsy, or insanity are accepted

THE SANITARIUM

REST, RELAXATION, MEDICAL CARE

The Sanitarium has all the atmosphere of a fine hotel with individual rooms and tasteful decorations A special feature is made of occupational therapy of all kinds with competent staff and facilities Other features are large cheerful solarium, billiard room, complete gymnasium, complete bath and massage department The spacious grounds include a nine-hole golf course All the sanitarium facilities are open to guests who do not wish examination and medical care, but come simply for the baths and massages and rest and recreation Modern medical equipment and superb location offer the combined advantages of a medical center and rural Spa

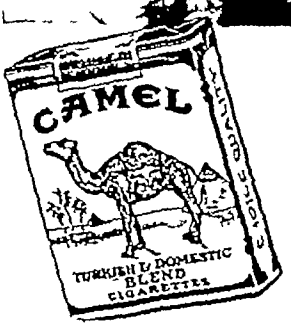
How mild can a cigarette be?

DOCTORS REPORT

In a recent test of hundreds of people who smoked only Camels for 30 days, noted throat specialists, making weekly examinations, reported

"NOT ONE SINGLE CASE OF THROAT IRRITATION DUE TO SMOKING CAMELS!"



SMOKERS REPORT

"I MADE THE CAMEL 30-DAY TEST AND I **KNOW!** CAMELS ARE THE MILDEST CIGARETTE I'VE EVER SMOKED— AND SO GOOD TASTING, TOO!"

Rita Edwards

TELEPHONE OPERATOR

R. J. Reynolds Tobacco Company Winston-Salem N. C.

According to a Nationwide survey:

More Doctors Smoke Camels

than any other cigarette

Doctors smoke for pleasure too! And when three leading independent research organizations asked 113,597 doctors what cigarette they smoked the brand named most was Camel!

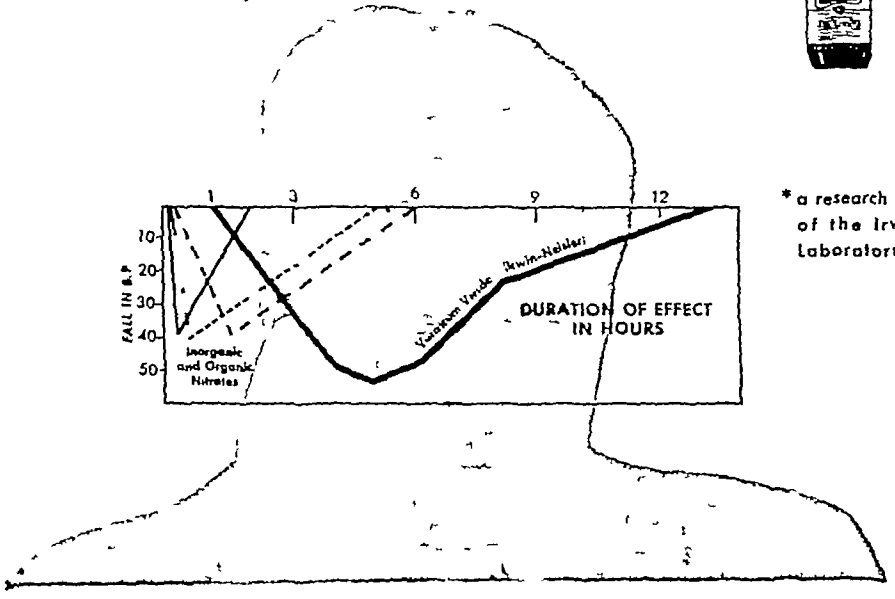
for a

PHYSIOLOGIC FALL

in blood pressure

Of the many drugs commonly used to lower arterial pressure in hypertension, Biologically Standardized veratrum viride (in CRAW UNITS*) is the only drug that produces a physiologic fall in blood pressure

Thus, a prominent feature in the integrated response to oral doses of veratrum viride in CRAW UNITS is a reduction in peripheral resistance without compromise of circulation and without disrupting circulatory equilibrium



VERATRITE represents a practical modification of this effective hypotensive drug for everyday management of the mild and moderate cases of essential hypertension

Prolonged action, wide range of therapeutic safety and complete simplicity of administration are specific advantages of Veratrite therapy. Each Veratrite Tabule contains Biologically Standardized veratrum viride 3 CRAW UNITS, sodium nitrite 1 grain, phenobarbital ¼ grain

Protein Hydrolysate, Baxter, contains the right combination of qualities necessary for successful parenteral protein feeding It is derived from proteins of high biologic value with all amino acids conserved, is non-antigenic and has a low concentration of dicarboxylic (nausea-provoking) amino acids It can be administered at a high rate of infusion, giving the patient more time to rest

Protein Hydrolysate is but one of the Baxter "right combination" solutions for parenteral therapy Baxter provides from one source and with standardized procedures the exact solution and the specific equipment for any parenteral requirement.

"We have never had other iron salts so efficacious..."[1]

In the treatment of hypochromic anemia the new molybdenum-iron complex, Mol-Iron, is being found to possess *marked advantages* over equivalent dosage of ferrous sulfate alone, or combined with liver-stomach extract or folic acid

Independent controlled tests[1 2 3] in relatively resistant iron-deficiency anemia of pregnancy have demonstrated a more rapid hemoglobin regeneration as well as greatly improved gastric tolerance

Investigators have commented "The increases in hemoglobin (with Mol-Iron) were dramatic and rapid,"[1] there was "more rapid response than with ferrous sulfate,"[2] "unusually effective and well tolerated in hypochromic anemia,"[3] "encouraging results obtained with molybdenized ferrous sulfate in the microcytic hypochromic group indicate a better prognosis in these conditions (pregnancy anemia) in the future"[4]

is pleased to announce that it has made available for use in the treatment of

PSORIASIS

SEVINON

specially purified undecylenic acid for oral administration

Attention has recently been drawn to 'an interesting approach"[1] to the control of psoriasis and neurodermatitis Perlman[2] has reported that following the oral use of undecylenic acid, psoriasis was relieved completely in 3 out of 17 patients, and was partially relieved in the remainder "Relief of itching is sometimes noticed as early as two days after institution of treatment undecylenic acid seems to hold a great deal of promise in the improvement and possible prevention of recurrences of psoriasis and neurodermatitis."[2]

SEVINON* is available in gelatin capsules containing 0 44 Gm. undecylenic acid, highly purified for oral use The dosage employed by Perlman[2] corresponds to 5 to 6 capsules three times daily by mouth, continued in some cases for as long as six months.

Physiologic Blockade against Hay Fever...

CHLOROTHEN

WHITTIER

At the height of the pollen season, with the atmosphere laden with billions of spores, antigenic provocation reaches its peak in the hay fever patient Now more than ever, he needs the assistance of potent long acting Chlorothen Whittier, to erect a defensive blockade against the effects of antigenic exposure

For the patient, selection of the right antihistaminic often spells the difference between normal living and utter wretchedness. Chlorothen, Whittier, provides potency of action combined with particularly long sustained effect thus ensuring full protection throughout the intervals between doses. Unwanted side-reactions are minimal in both incidence and severity and can frequently be combatted by simple adjustment of dosage

The wide sphere of use of Chlorothen, Whittier includes, in addition to hay fever, vasomotor rhinitis urticaria, angioneurotic edema, atopic dermatitis and other allergic manifestations

To facilitate rapid solution and absorption and hence prompt action, Chlorothen Whittier, is issued as uncoated tablets of 25 mg each for oral administration One to two tablets every 4-6 hours, according to the response is the customary dosage range

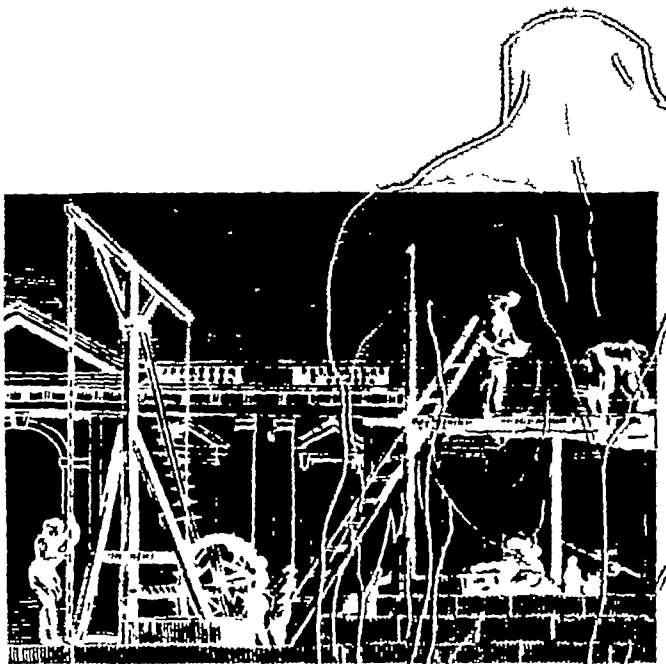
Chlorothen Whittier: Packaged in bottles of 100 tablets 25 mg per tablet

Whittier LABORATORIES

highly effective in an unusually wide range of common skin disorders

Pragmatar is particularly useful in seborrheic dermatitis, and in the general care and hygiene of the seborrheic scalp

Pragmatar often brings dramatic improvement in the common fungous infections—even in "athlete's foot"



Pragmatar is extremely valuable in eczematous eruptions, especially those in which a seborrheic factor is involved

Smith, Kline & French Laboratories, Philadelphia

Pragmatar

the outstanding tar-sulfur-salicylic acid ointment

Building stones

Tissue repair is the keystone of the recovery process It makes little difference if the infection is halted, the fracture reduced, or the metabolic imbalance adjusted—it is the *patient's own cells* that must complete the cure

While true hypoproteinemia is comparatively rare, nevertheless hypernutrition with essential amino acids during the recovery process has been shown empirically to speed the patient upon the road to normal health Amino acid preparations should be supplemented by moderate amounts of vitamins

Lederle research has for some time been concerned with such mixtures of amino acids and vitamins and their application in the field of nutrition

LEDERLE LABORATORIES DIVISION AMERICAN Cyanamid COMPANY 30 ROCKEFELLER PLAZA • NEW YORK 20 N. Y

Aluminum

PENICILLIN*

ORAL TABLETS

Aluminum Penicillin Oral Tablets are clinically effective in the treatment of penicillin susceptible infections

Containing the almost insoluble trivalent aluminum salt (not a mixture), they provide for maximum utilization of the dose administered

Low solubility of Aluminum Penicillin renders it much less liable to inactivation in the stomach Destruction in the intestinal tract is inhibited by the addition of sodium benzoate Slow conversion to a readily absorbed form in the more alkaline conditions of the intestinal tract enhances clinical effectiveness

Aluminum Penicillin is not toxic in doses far exceeding those used therapeutically and does not cause gastric disturbance.

Specify Aluminum Penicillin Oral Tablets, H. W & D

Supplied in vials of twelve tablets each containing Aluminum Penicillin, 50,000 units, and sodium benzoate, 0 3 gram

* Patent applied for

Oral Tablets *Now Council Accepted*

when headache is a problem
Edrisal is the logical answer

" ... in the vast majority of patients psychologic factors are present which tend to increase the frequency and severity of headaches "

Friedman, A P , and Brenner, C N Y State J Med 45 1969

Edrisal is remarkably effective in headache, even in difficult psychogenic cases For Edrisal is the only analgesic preparation that contains 'Benzedrine' Sulfate—the rational anti-depressant Edrisal, therefore, not only relieves the pain itself but also—by lifting your patient's mood—relieves his concern with pain Best results are usually obtained with a dosage of *two* Edrisal Tablets—repeated every three hours, if necessary

Smith, Kline & French Laboratories, Philadelphia

Edrisal its dual action relieves pain, lifts mood

Each Edrisal tablet contains Benzedrine* Sulfate (racemic amphetamine sulfate, S K F), 2 5 mg , acetylsalicylic acid, 2 5 gr , and phenacetin, 2 5 gr*
Available on prescription only

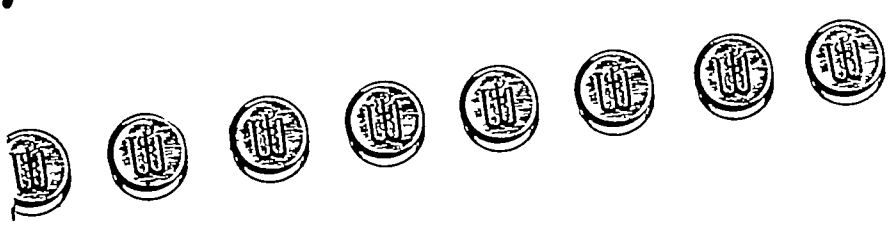
RESMICON™

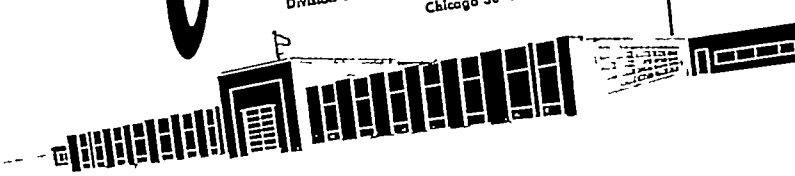


acid-adsorbent demulcent

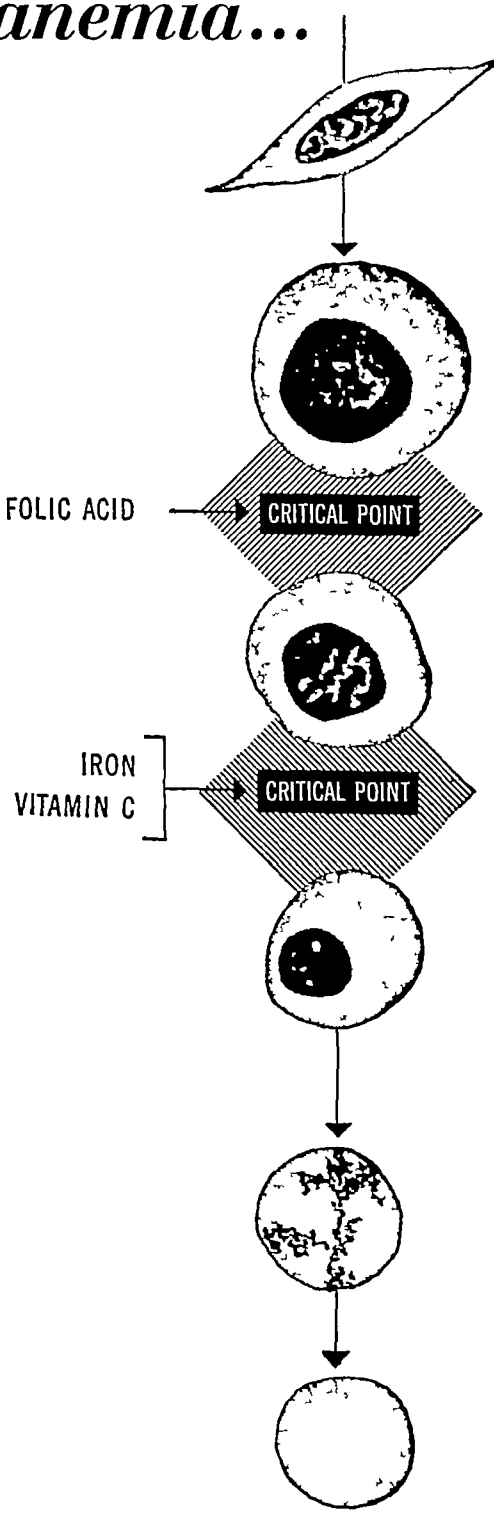
without side effects

BECAUSE Resmicon combines anion exchange polyamine resin with natural gastric mucin This combination means double-barrelled action for relief of pain and promotion of healing in peptic ulcer.

BECAUSE Resmicon's polyamine resin inactivates hydrochloric acid by physical adsorption, not by chemical "neutralizing" or "buffering" This physical action induces no alkalosis, no acid rebound, no depletion of body electrolytes, no formation of renal calculi, no toxic effects, no irritation, and no uncomfortable side effects such as constipation, diarrhea, eructation, or flatulence



for effective peptic ulcer therapy



BECAUSE Resmicon's mucin provides a dense, tenacious coating for the eroded area, as well as for the whole gastric mucosa This mucinous film—highly resistant to penetration by HCl and pepsin—protects the ulcerated tissue and fosters healing

RESMICON tablets gastric mucin, 170 mg anion exchange polyamine resin, 500 mg , supplied in bottles of 84 tablets

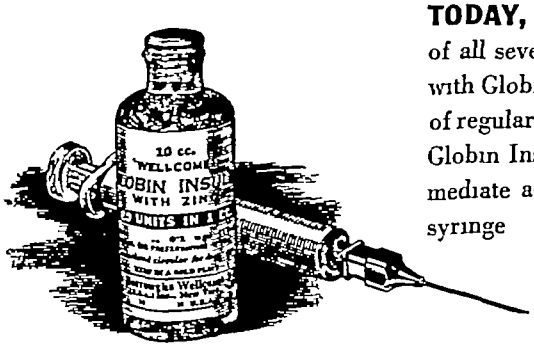
INTERMEDIATE ACTING

GLOBIN INSULIN

'B.W.&CO.'



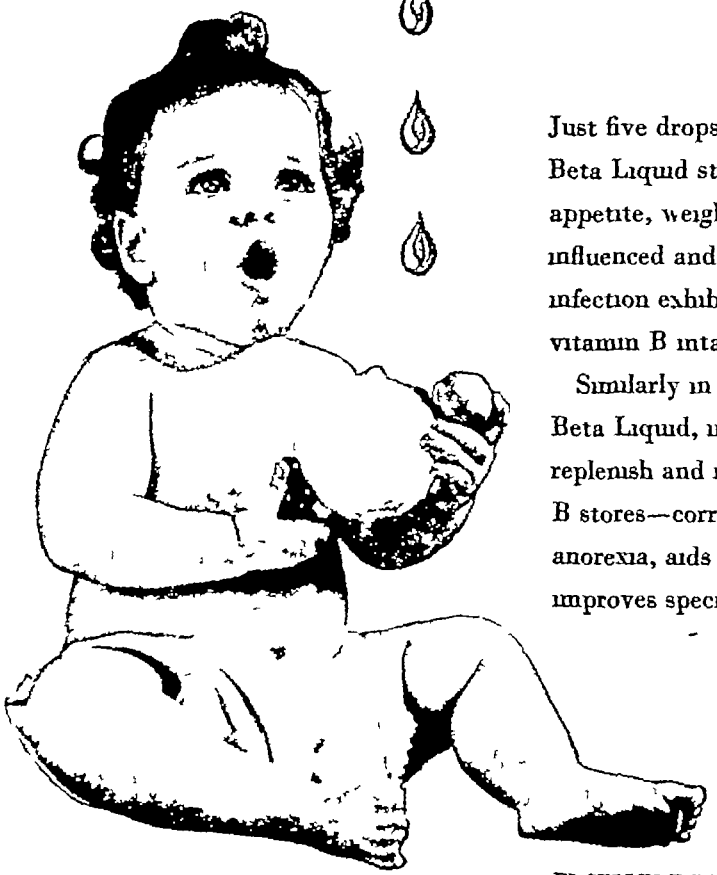
was developed to fill the "need for an insulin with activity intermediate between that of regular insulin and that of protamine zinc insulin"[1]

IN 1939, Reiner, Searle and Lang described a new "intermediate acting" insulin

IN 1943, after successful clinical testing, the new substance was released to the profession as 'Wellcome' brand Globin Insulin with Zinc 'B W & Co'

TODAY, according to Rohr and Colwell, "Fully 80% of all severe diabetics can be balanced satisfactorily"[2] with Globin Insulin 'B W & Co'—or with a 2 1 mixture of regular insulin protamine zinc insulin *Ready to use* Globin Insulin 'B W & Co' provides the desired intermediate action without preliminary mixing in vial or syringe

In 10 cc vials U-40 and U-80



'B.W & CO'—*a mark to remember*

FROM SECRETARY OF DEFENSE LOUIS JOHNSON—

AN URGENT APPEAL TO YOUNG DOCTORS!

Your personal help is needed to avert a serious threat to our national security!

By the end of July of this year we will have lost almost one-third of the physicians and dentists now serving with our Armed Forces Without an increased inflow of such personnel, the shortage will assume even more dangerous proportions by December of this year

These losses are due to normal expiration of terms of service The professional men who are leaving the Armed Forces during this critical period are doing so because they have fulfilled their duty-obligations and have earned the right to return to civilian practice

Without sufficient replacements for these losses, we cannot continue to provide adequate medical and dental care for the almost 1,700,000 service men and women who are the backbone of our nation's defense

Normal procurement channels will not provide sufficient replacements!

To alleviate this critical, impending shortage of professional manpower in the three services, I am urging all physicians and dentists who were trained under wartime A.S T P and V-12 programs under government auspices or who were deferred in order to complete their training at personal expense, *and who saw no active service*, to volunteer for a two-year tour of active duty, at once!

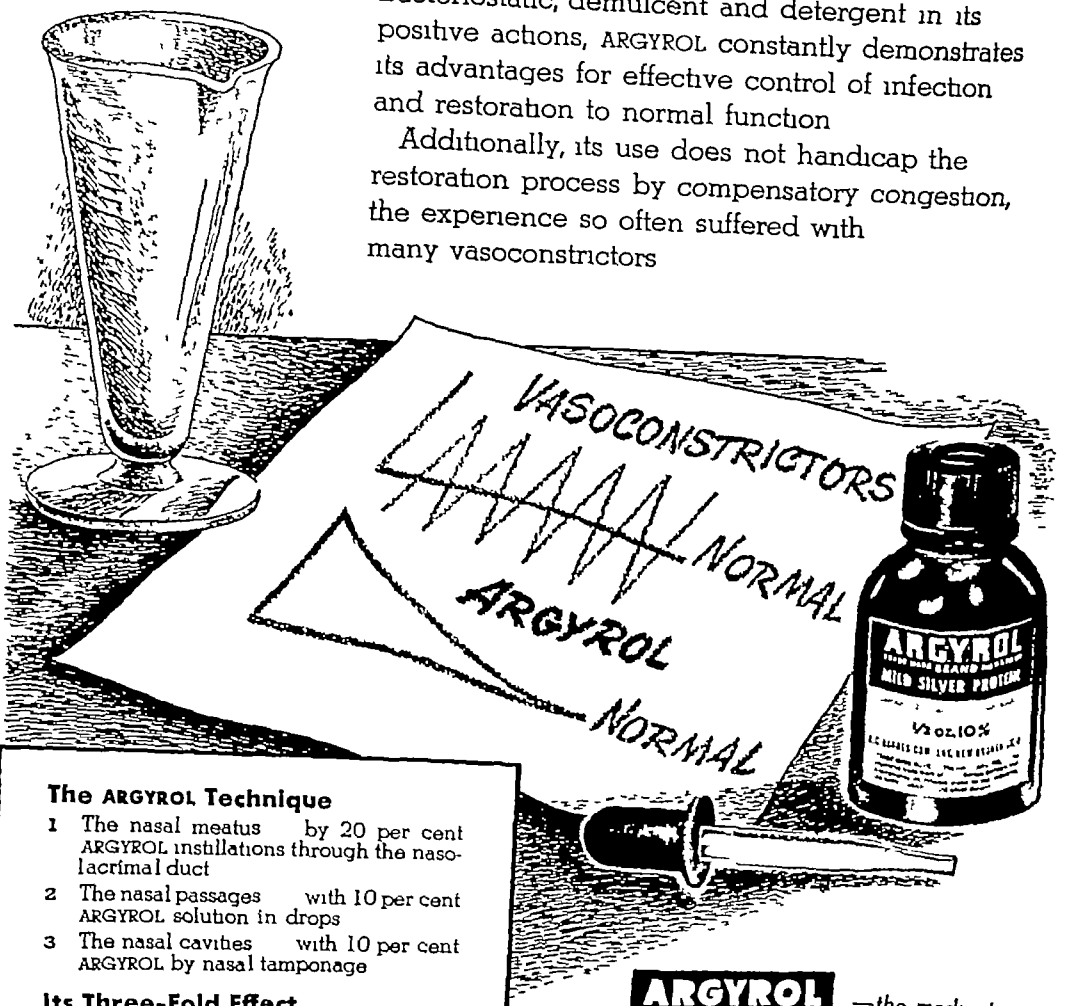
We have written personally to more than 10,000 of you in the past weeks urging such action The response to this appeal has not been encouraging, and our Armed Forces move rapidly toward a professional manpower crisis!

Many responses have been negative, but worse—a great number of doctors have not replied It is urgent that we hear from you immediately!

We feel certain that you recognize an obligation to your fellow men as well as to your profession in this matter We are confident that you will fulfill that obligation in the spirit of public service that is a tradition with the physician and dentist.

There is much to be said for a tour of duty with any of the Armed Forces You will work and train with leading men of your professions. You will have access to abundant clinical material, have the best medical and dental facilities in which to practice You will expand your whole concept of life through travel and practice in foreign lands In many ways, a tour of service will be invaluable to you in later professional life!

Volunteer now for active duty You are urged to contact the Office of Secretary of Defense by collect wire immediately, signifying your acceptance and date of availability Your services are badly needed. Will you offer them?



Louis Johnson

In Treating Para-nasal Infection **ARGYROL** Affords

multiple action without reaction

Bacteriostatic, demulcent and detergent in its positive actions, ARGYROL constantly demonstrates its advantages for effective control of infection and restoration to normal function

Additionally, its use does not handicap the restoration process by compensatory congestion, the experience so often suffered with many vasoconstrictors

The ARGYROL Technique

1 The nasal meatus by 20 per cent ARGYROL instillations through the naso-lacrimal duct
2 The nasal passages with 10 per cent ARGYROL solution in drops
3 The nasal cavities with 10 per cent ARGYROL by nasal tamponage

Its Three-Fold Effect

1 Decongests without irritation to the membrane and without ciliary injury
2. Definitely bacteriostatic yet non toxic to tissue
3 Stimulates secretion and cleanses thereby enhancing Nature s own first line of defense

ARGYROL —*the medication of choice in treating para-nasal infection*

Tenure of Hospital Staff Appointments

The House of Delegates of the Medical Society of the State of New York at the annual meeting this year considered the matter of tenure of hospital staff appointments It was voted that "an appropriate committee, working in conjunction with other interested groups initiate studies to define just and uniform standards for dealing with problems relative to tenure of hospital staff appointments, and other pertinent matters relative to staff appointments" Also "that proper and equitable hospital administration should include provisions in hospital bylaws to protect staff appointments of physicians from capricious or summary termination "[1]

The Planning Committee for Medical Policies initiated the recommendation in its annual report, and it may well be that such studies may lead to a clearer understanding by all parties at interest, especially if precedent cases adjudicated in the courts are thoroughly studied

A case in point is that of *Van Campen v Olean General Hospital*, in which the plaintiff physician who was dropped from the staff alleged "arbitrary and confiscatory action" on the part of the hospital He received notice that by action of the board of directors he was dropped from the visiting staff, with the privilege of treating his patients then in the hospital

Mr Justice Davis of the Court of Appeals, in reversing the lower court which found for the appellant physician, expressed the unanimous opinion of his colleagues in dismissing the complaint [2] In his discussion he brought out many points of interest to physicians

1 The plaintiff physician alleged that the defendant hospital was a "public corporation" This view was sustained by the lower court, but was not held by the Court of Appeals Said Mr Justice Davis

2 His (the plaintiff's) claim is that he has been deprived of the right to use in his business the property of another, the defendant

3 The learned trial court has found and the judgment declares that the defendant is a public corporation With due deference we cannot take

[1] Minutes of the House of Delegates 1949

[2] Opinion reported in 210 A.D 204 and affirmed by the Court of Appeals in 239 N Y 610

that view Public corporations are the instrumentalities of the State, founded and owned by it in the public interest, supported by public funds and governed by managers deriving their authority from the State

There are many public institutions in this State devoted to the care of afflicted and unfortunate people They may be conducted directly by the State or they might be made by statute corporate bodies, like school trustees of boards of education Hospitals may be established by certain municipalities These are public hospitals Corporations organized by permission of the Legislature undertake to perform similar duties They are supported mainly through voluntary gifts These are private corporations *That they are engaged in charitable work for the benefit of the public and thereby affected with a public interest does not make them public corporations The fact that they may receive a donation from the government to enable them to carry on their work, or funds from a city or county to care for sick and disabled indigent persons does not affect their character as private institutions*

Defendant is a nonstock corporation, its organization made possible by an act of the Legislature which determines the manner of electing its directors and provides a method of a new election Its affairs are in many respects regulated by statute Its incorporation was originally contingent upon the written approval of the State Board of Charities and of a justice of the Supreme Court of the district Its directors and officers may receive no pay except under certain circumstances It is subject to visitation, inspection, and supervision by the State Board of Charities

While such a corporation is exempt from liability for negligence to patients and is granted exemption from taxation, *these facts do not indicate that the corporation is public* Exemption from taxation is given by the Legislature to many corporations and individuals as a matter of public policy

We must then consider whether the plaintiff had any vested right to use the property of this private corporation for his own gain, and whether a court of equity has jurisdiction to intervene so far in the management of the hospital that it may give plaintiff redress for what he claims were arbitrary and capricious acts of the directors

It is unnecessary to recite the differences between plaintiff and those in active charge of the hospital The trial justice aptly described them as "petty" Whether these complaints were well founded or not it is unnecessary to consider That complaints of mismanagement and neglect will always be made in such institutions is inevitable There were counter-complaints that plaintiff did not comply with the rules and regulations adopted for the hospital management Evidently the directors eventually came to regard plaintiff as a disturber of the harmony of the institution The notification of his being dropped from the visiting staff followed

Inasmuch as the Reference Committee on the Report of the Planning Committee for Medical Policies suggested that "proper and equitable hospital administration should include provisions in hospital bylaws to protect staff appointments ," the following remarks of the learned Justice will be found of interest

Just what is meant by the "visiting staff" is not entirely clear Portions of the bylaws are printed in the record One states that "the medical staff shall be composed of resident practicing physicians and surgeons of Cattaraugus County" who are members of the hospital It does not say the staff shall include *all* such physicians and surgeons Another bylaw provides that *if the board of directors shall determine that the character, conduct, or acts of any member of the medical staff are such as to interfere with the orderly conduct of the hospital, the board may by resolution remove or suspend him*

Of especial significance to anyone who questions the powers of hospital governing boards is the following

There is no provision in the bylaws for a hearing prior to removal or suspension We think none is required The selection and retention of physicians to treat patients admitted to the hospital are matters of judgment and discipline The power to appoint usually implies the authority to remove In common experience instances are not unusual where some physician disagrees with hospital management When such disagreement becomes so pronounced as to interfere with orderly management and discipline, and when there is persistent violation and disobedience of necessary rules and regulations, *we think the directors may bring the inharmonious conditions to an end by summary action They are not required, in our judgment, to give notice and conduct a trial in every such case* Public-spirited citizens, usually having business of their own, who act as directors without pay, having many duties relative to finance and management, would no doubt find their time fully occupied if the duty of holding trials on all sorts of complaints was superadded If, in every detail of management involving the relation of the hospital with the physician and patient, they have no power of final decision but

must be guided and directed by orders and judgments of the court therein, *then their duties are little more than perfunctory*

The management of such corporations is given by law to the board of directors It is a power delegated by the Legislature The authority of the directors of membership corporations to deal with property is restricted Otherwise, their duties are similar to those of directors of other corporations and similar principles apply

Directors hold office charged with the duty to act for the corporation according to their best judgment, and they cannot be controlled in the reasonable exercise and performance of such duty They have wide discretion in determining policies, and its exercise in a given matter is not subject to review by the court unless there is clearly error in the performance of a legal duty Equity will not attempt to correct errors of judgment, for courts have nothing to do with the internal management of corporations in the absence of fraud or bad faith if kept within corporate powers

The law does not require a corporation like defendant to furnish its services and accommodations to every one who applies, whether patient or physician There can be no absolute right in individuals to claim the benefit of its privileges Such a thing would be impossible There must be discretion vested in the management to make selection from applicants with regard to accommodations available It may reject one who has some trivial ailment, and accept another whose needs are greater This is not illegal discrimination depriving a person of his rights, nor do we deem it such discrimination if from a large number of physicians it selects members of its visiting staff with regard not only to their medical skill, but to their adaptability to the rules and discipline of the institution

The usual remedy for persons dissatisfied with the internal management of corporate affairs is to elect a new board of directors If the acts of the directors are generally regarded as arbitrary and unjust, contributions, without which the hospital cannot operate, will be withheld, and public opinion, the most potent regulator of public affairs, will furnish the remedy

We cite this case in extenso, believing that it covers many points of interest relative to the relationship of hospital visiting staffs and hospital governing boards

Retirement of an Editor

The prospective retirement of Dr Morris Fishbein as editor of the *Journal of the American Medical Association* will be viewed with sincere regret by all those who know him For thirty-six years Dr Fishbein has devoted his extraordinary abilities to the improvement of medical journalism in the United States and has created a publication outstanding in the medical literature of the world

In 1913, Dr George H. Simmons, then editor of the *Journal*, went abroad for his vacation Dr E E Hyde, assistant to the editor, and acting editor during Dr Simmons' absence, died suddenly of myelogenous leukemia On August 27 of that year Dr Fishbein had commenced his work with the Association replacing Dr Hyde. Dr George Simmons had obtained his services on the recommendation of Dr Frank Billings and Dr Ludvig Hektoen Dr Fishbein served as assistant editor until Dr Simmons' retirement in 1924 when the latter was made editor emeritus During this period, 1913 to 1924, the editorials in the *Journal* were mostly the responsibility of Drs Lafayette Mendel, Ludvig Hektoen, and Morris Fishbein

In 1924 also, the offices of editor of the *Journal* and general manager of the A M A were separated on the ground expressed by Dr Wells P Eagleton of New Jersey that "the editor should devote his entire time to the scientific and ethical aspects of the profession, not to its business"[1] This, Dr Fishbein has done not only as editor of the *Journal* but in the advancement of medical education, improvement of hospitals, and the suppression of quackery

In 1949, by resolution of the Board of Trustees of the A M A , Dr Fishbein was relieved of many of his other activities

---

[1] History of the A M A Philadelphia W B Saunders Co 1947 p 340

Hereafter the editor will confine his time exclusively to the scientific aspects of the Association and will not be available for public talks except on scientific subjects

Those being trained by Dr Fishbein as successors to his other jobs are Dr Richard J Plunkett, associate editor of the *Journal*, who will become editor of the nine specialized medical journals published by the A M A , Dr W W Bauer, director of the Bureau of Health Education and associat *Hygeia*, health magazine for the slated to be editor of the latte Magdaline Freyder, A M A hb will become editor of the quarte *tive Index Medicus* Dr Austin retary of the Council on Pha Chemistry of the A M A , ha training as the assistant edit *J.A M.A*

Production and Distribution of Isotopes

The year 1948 was the golden anniversary of Pierre and Marie Curie's discovery of radium Also, 1948 was the silver anniversary of the use by Hevesy, in Denmark, of radioactivity to trace the course and behavior of a stable element in a biologic system Then, in 1934, came what Aebersold calls the "miraculous discovery" by Curie and Joliot that nearly all ordinary stable elements can be induced to become radioactive [1]

The man-made radioisotopes at first could be made only in limited quantities at considerable expense by atom-smashing cyclotrons The new world of opportunities in medical research and application came only with the first successful chain reaction in uranium, developed by the wartime atomic energy project, known as a "nuclear reactor" or "atomic pile" Not until June, 1946, was it announced that pile-produced radioisotopes would be made available to those outside the atomic energy project

Within two years, in May, 1948, shipments of isotopes were at the rate of over 200 per month, to 119 institutions in thirty states and to fourteen foreign countries Individual projects in all fields of study number over 1,400, of which studies in medicine and biology total over 700 The isotopes most commonly used in physiologic studies are iodine 131, phosphorus 32, and carbon 14 In addition sulfur 35, sodium 24, potassium 42, iron 55 and 59, and calcium 45 have been used extensively Isotopes used in limited quantities for experimental therapy include gold 198, silver 110, copper 64, zinc 65, strontium 89, and cobalt 60 The fields of study embrace diagnosis, treatment, and research in metabolism, physiology, and pharmacology The Atomic En mission has made available tw radioisotopes of twenty elements in biologic and medical studies b gators in foreign countries S have been made to fourteen where impressive results are re more than a hundred individual p

The greatest present need is semination of detailed available tion on laboratory procedures o applications, and for training n scientists The Commission's C Technical Information provides on classified information, also it unclassified information and has n a system of fellowships for tra atomic energy development Ph are urged to write to the Isotope I Atomic Energy Commission, Oak Tennessee, concerning available n tion and assistance on whatever p they think may best be appl through the use of isotopes

The Baby Book

The State Depa of Health has issued an excellent in tive booklet for the laity under the title It has had a most favorable tion, judging from the fact that th edition of 110,000 copies was exhaust most immediately, and additional pri ordered, and from the many expressi praise received by the State Departi Through the various local health de ments and regional offices, the booklet offered to all hospitals in the upstate for distribution to their obstetric pati

The State Society's Committee on P Health and Education took an active in an advisory capacity in the prepara of the book *The Baby Book* should ser useful purpose for the instruction of prosp tive mothers in the care of infants

DEVELOPMENTS IN PUBLIC HEALTH

From the New York State Department of Health

William A Brumfield, Jr , M D , Editor

Tuberculosis Control Program in New York State Institutions for the Mentally Ill

In 1941 the Departments of Health and of Mental Hygiene of New York State inaugurated a tuberculosis control program in mental institutions in an effort to lower the high morbidity and mortality rates and to prevent the transmission of infection

Initial case-finding surveys conducted at the hospitals for the mentally ill, the schools for the mentally defective, and Craig Colony for Epileptics were completed in 1944 and revealed prevalence rates many times higher than those of the general population At the hospitals, 4,133 of the 73,658 patients examined, and at the schools and Craig Colony, 377 of the 15,400 patients examined showed x-ray evidence of clinically significant pulmonary tuberculosis for prevalence rates of 5 6 per cent and 2 4 per cent, respectively A prevalence rate of 1 1 per cent was found for the 14,000 employes x-rayed at the hospitals, and a rate of 0 7 per cent for the 2,768 x-rayed at the schools and Craig Colony

The prevalence rates in the fifteen to nineteen year age group were higher for females than for males, in all other age groups the rates were consistently higher for males than for females In the schools the rates were higher for females than for males up to the thirty-five to forty-four year age group, above which the rates were higher for males When the length of the interval between first admission to a State mental hospital and the date of the initial x-ray survey was taken into consideration, it was found that prevalence rates were higher for patients with longer time periods following first admission It was noted also that in the hospitals where prevalence rates for patients were high they tended to be high for employes, and when the rates were low among patients they tended to be low among employes

The communicability of tuberculosis, fostered as it is in these institutions by such factors as overcrowding and the inability of the patients to observe prophylactic measures, necessitates the provision of separate buildings for the segregation and care of infectious cases At present only a few institutions have buildings used solely for their tuberculosis patients, some have separate wards in buildings housing nontuberculous patients, and others have no facilities and therefore transfer their tuberculous patients to the institutions where special beds are available Plans are now being made for the construction of new buildings and for the remodeling of existing buildings to provide conveniently located hospital centers to be used exclusively for the segregation and care of all cases of clinically significant tuberculosis By this means tuberculous patients would be completely segregated from the nontuberculous, and the relative number of employes subjected to the hazard of exposure to active cases would be decreased

Immediately following the initial survey at each institution a routine was established whereby chest x-rays would be made, from that time on, of all candidates for employment and of all newly admitted or readmitted patients From the time this routine was started in each institution, through 1946, figures showed a prevalence rate of 0 8 per cent of clinically significant tuberculosis among applicants for employment Among 12,794 patients newly admitted to 20 institutions, 351 were found to have clinically significant pulmonary tuberculosis, for a prevalence rate of 2 7 per cent When candidates for employment are found to have clinically significant tuberculosis, they are referred to tuberculosis hospitals for study and treatment, permanent ap-

pointment is not granted until evidence of the inactivity of the disease process is presented Patients found to have x-ray evidence of infectious disease are promptly segregated

The original and ideal plan to conduct resurveys at yearly intervals at all of the institutions has not been possible because of insufficient personnel However, resurveys conducted over a period of five years, with intervals ranging from more than two years to more than four years, are now nearly completed and indicate an average incidence rate of approximately 0 4 per cent per year for patients on the general wards In a special study of the incidence of pulmonary tuberculosis among employes in 13 institutions, the rate for employes in the hospitals was 0 1 per cent per year, which is approximately the same as the estimated rate for the general population of the State.

A system to supply basic data for clinical, statistical and epidemiologic studies has been established Provision has been made also for follow-up examinations, by local health departments, of discharged tuberculous patients, of tuberculous patients on convalescent status, and of their contacts

Preliminary studies in penal and correctional institutions indicate that tuberculosis prevalence rates for inmates, although not so high as for patients of mental hospitals and schools, are higher than those for the general population A control program, therefore, similar to that of the mental institutions, is now being proposed for the institutions of the State Department of Correction

THE ULCERATIVE COLITIS PROBLEM

ALBERT F R ANDRESEN, M D , Brooklyn, New York

WHILE ulcerative colitis is not a very common disease, the treatment of a stubborn case is such a serious problem that a large number of articles on this subject is accumulating in the literature, each author's opinions differing so radically from those of other equally qualified contributors that the practitioner attempting to treat a case is today in a state of confusion Attempting to treat a diarrheal case with the usual bismuth and opium mixture or one of the newer antidiarrheal preparations and using suppositories or ointments if bleeding occurs, the practitioner finds his patient not improving and, in fact, going steadily down hill Turning to his medical journal, textbook, or drug literature, he finds justification for the use of any number of remedies which have been recommended by authorities on the subject of ulcerative colitis Over the years he has, without success, thus tried fever therapy, Bargen vaccine and serum, the various sulfonamides as they came out, a succession of antibiotics, and various organic preparations and hormones, trying each new one as it became available Unsuccessfully treated patients travel from clinic to clinic and, if they can afford it, from city to city to consult with the experts Many of my patients have been to one or more such medical centers at New York, Boston, Philadelphia, Baltimore, Chicago, and Rochester, Minnesota, getting different treatments and advice without permanent benefit I have seen patients with 20 to 30 bloody discharges per day, emaciated, dehydrated, suffering from various food deficiencies, who have been prattled to about personality changes and control of emotional factors In recent years an increasing number of these patients are being subjected to ileostomy, with or without colectomy, the surgeons pointing with pride to the fact that these unfortunate creatures are able to marry and procreate even with such an impediment to romance An evaluation of the whole problem would seem to be in order and should consist first of a discussion of pathology and etiology, which must determine the nature of the treatment in any disease

Pathology

The term "ulcerative colitis" does not embrace a pathologic entity Ulcers due to specific organisms with surrounding or generalized colitis may occur in any part of the colon The dysenteries are really colitides, due to bacteria of the Shigella group or to Entameba histolytica Acute infections with Salmonella organisms and with Bacillus pyocyaneus produce an ulcerative colitis which may become chronic Lymphopathia venereum, syphilis, tuberculosis, and direct infection of the bowel wall with pyogenic organisms may also produce what, in the general sense, may be called ulcerative colitis Even the presence of an ulcerating carcinoma will produce a surrounding colitis, and it is sad to relate how frequently patients with carcinoma are treated as ulcerative colitis cases until going beyond the stage of operability As a rule today, when speaking of ulcerative colitis, we mean a disease which runs a definite course but for which no specific organism has been found responsible and whose cause is in dispute—hence the term "idiopathic ulcerative colitis" Kantor suggested the term "colitis gravis" as a better name [1]

The pathologic lesions of such an ulcerative colitis occur in stages and may at first be found only in one segment of the bowel, often the rectum and sigmoid, and may remain localized there or spread later to the entire colon and even to the terminal ileum

In the early stages hyperemia, hypersecretion, and mucosal edema are present, and a punctate rash, resembling herpes, is usually seen As a result of localized ischemia, areas of necrosis develop and slough out, leaving ulcerated areas which, when they coalesce, cause

Presented at the 143rd Annual Meeting of the Medical Society of the State of New York Buffalo Section on Gastroenterology and Proctology May 5 1949

extensive areas of denudation of mucosa with small islands or tabs of mucosa still visible These denuded areas may bleed upon slightest trauma or the sloughing out of the walls of small blood vessels may produce more profuse bleeding Very deep sloughing may produce single or multiple perforations with resulting local or general peritonitis and later adhesions, deformities, kinks, or obstructions Induration with infiltration by leukocytes, often demonstrable as eosinophils, may disappear with healing or may result in fibrosis with marked narrowing or stiffening and shortening of the colon The mucosal lesions may disappear entirely, or with long continued irritation islands of mucosal remnants may undergo polypoid changes in which carcinoma may, but does not often, develop More or less bacterial invasion may be found in the tissues, and *lymphadenitis may be demonstrable in the* mesenteric glands The early changes described above are identical, both grossly and microscopically, with the changes described by Gray, Walzer, Harten, and their associates They reported on their experimental work in gastrointestinal allergy, using the mucosa over human hemorrhoids and colostomies and the intestinal walls of the Rhesus monkeys, sensitized by passive transfer, to observe the pathologic changes caused by ingestion of the food to which the tissues had been sensitized [2-4] These changes were produced by a single swallow of the antigen It can easily be imagined what the effect of such insults frequently repeated would be in producing the more extensive changes seen in the severe cases

Etiology

There is a surprising difference of opinion as to the cause of ulcerative colitis Due to the fact that, except in the cases of specific organisms mentioned before, the colon bacillus is usually the only or the predominant organism found, it was assumed for a time that in some individuals it could become pathogenic The enterococci, normal inhabitants of the ileum and usually not viable in the colon except where carried through it rapidly as a result of diarrhea, were next implicated, and the Bargen diplococcus, one of this group, was considered specific Various other organisms, viruses, and fungi have been suggested at different times The fact that the disease occurred in many patients who had previously had dysentery implicated the dysentery organisms The food and vitamin deficiencies, actually the result of a lack of absorption, impelled some clinicians to include ulcerative colitis among the deficiency diseases The usual neuropsychiatric manifestations which should be expected to occur in patients with such severe gastrointestinal symptoms have been interpreted by the psychiatrists as the causative factors, and in some cases specific changes in colonic innervation have been postulated The often dramatic relief of all symptoms following eradication of focal infections has resulted in efforts at isolating a specific organism in the foci, without result The only factor which I have found to be almost invariably the cause of this disease has been allergy, usually to foods, although occasionally pollens, dusts, bacteria or their products, and endocrine or hormonal secretions would seem to be the allergens to which the patient has become sensitized The proof of the role played by the specific substances is not a simple matter It requires patience and thoroughness on the part of physician and patient to establish the cause or causes, but once these have been found, their effect on the bowel, as seen by roentgen study and proctoscopy, is very convincing And theoretically, comparison of the conditions in the intestine with those in another well-known shock organ, the respiratory tract, helps to explain a number of the conditions encountered in ulcerative colitis In asthma, for instance, severe, specific, acute infections often precede the onset of the original allergic symptoms, secondary infections may result in a masking of the cause, removal of focal infections will occasionally result in cure, neuropsychiatric symptoms abound and when, instead of occurring periodically the symptoms become constant and severe marked changes usually follow

Diagnosis

The history is important A family or previous personal history of some form of allergy is suggestive The onset of the disease may occur in several ways

1 It may be preceded by a more or less long-continued history of attacks of diarrhea or other abdominal symptoms, often attributed to specific dietary indiscretions, the patient stating that milk or coffee or some other food has acted as a laxative or cathartic

2 There may be a gradual onset with mild diarrhea in the early stages, gradually becoming more severe, and with bleeding becoming increasingly noticeable

3 The symptoms may occur sooner or later after an acute dysentery or an acute gastroenteritis or food poisoning

The symptoms are readily explainable on the basis of the pathologic findings The allergic

reaction in the mucosa causes spasms and hypermotility which produce pains, tenesmus, and diarrhea, the number of loose or watery stools varying from three or four to 20 or 30 per day The sloughing and exfoliation with bleeding and excessive production of mucus add blood and mucus to the stools and eventually will result in frequent bloody rectal discharges independent of fecal admixture, the patient often having actually only one real stool in twenty-four or forty-eight hours while 30 to 40 of the bloody rectal discharges are taking place per day

Anorexia, disgust for food, and the nervous symptoms, including a marked depressive state, resulting in insufficient food intake, the failure of digestive secretions, and the rapid progress of food over the diseased intestinal mucosa preventing adequate absorption, all combine to cause emaciation, dehydration, and evidences of food and vitamin deficiencies Absorption of toxic materials from the denuded areas and secondary infection will produce fever, adenopathy, and toxic symptoms The neuropsychiatric symptoms which may at first interfere with care of the patient often change for the better with unbelievable rapidity as the patient's general condition improves under proper care Complications cause serious symptoms Mesenteric lymphadenitis produces symptoms which may suggest an acute abdomen, and perforation, while rare, may be rapidly fatal I saw a patient who died following perforation of an old sigmoid diverticulum

Physical Examination—Abdominal examination may disclose nothing abnormal, may show distention, localized or general tenderness, or rigidity, and at times the thickened or spastic colon may be palpable and tender General examination will usually show the presence of focal infections, evidences of allergic reactions in the skin or other parts of the body, and in severe cases will disclose the marked emaciation, dehydration, and evidences of food, vitamin, and mineral deficiencies already mentioned It is important to ascertain at the start whether the patient has any organic lesions in any part of the body so that complications may be guarded against and treated early if they develop Search for focal infections in mouth, nose and throat, pelvis, and genitourinary tract should be thoroughly carried out

Rectal Digital Examination—This may show sphincter spasm which may later be changed to marked relaxation producing incontinence Hemorrhoids usually develop and may become so large as to require treatment Cryptitis occasionally associated with markedly enlarged papillae, which may protrude, are also distressing complications Rectal fistulas are frequently found The digital examination may also disclose strictures, polyps,and pelvic tumors, and in many cases previously treated for ulcerative colitis we find a hard, irregular carcinomatous infiltration

Proctoscopic Examination.—The findings in typical ulcerative colitis are those which were described in discussing the pathology of this disease In severe cases only a bleeding surface, looking like raw meat, will be seen, coated with blood and mucus and sloughing mucosa and showing yellowish pus discharges only where secondary infection has occurred These findings are in contrast with the discrete ulcers of amebic dysentery, scrapings from which will show motile amebae with enclosed blood cells and the multiple, small or coalescent ulcers with marked purulent and bloody exudate seen in bacillary dysentery Tuberculous and syphilitic ulcers and the lesions of lymphopathia venereum, which may be somewhat confusing because of their variability, are usually accompanied by other general manifestations of these diseases, and appropriate tests will establish the diagnosis Rectal and sigmoid carcinoma which often produce symptoms similar to ulcerative colitis must be ruled out Through the proctoscope biopsy specimens may be removed Smears should be prepared from scrapings, particularly to search for carcinoma cells or for the eosinophils so frequently seen in the ulcerative colitis, and material for cultures and further cytologic studies should be obtained by means of long pipets, syringes, or sterile swabs protected from contamination in long sterile tubes Repeated proctoscopies are a guide to improvement under treatment and to the effects of feeding of suspected allergens

Roentgen Examination—An opaque enema study should not be the full extent of the examination unless it has shown a definite obstruction of the colon A careful gastrointestinal series with films taken at frequent intervals after the barium meal will show the often concomitant small intestinal lesions or the effects of food and vitamin deficiencies The highly irritable colon may be empty in twenty-four hours, but at times the induration, adhesions, polyposis, or other changes may cause marked delay of the barium meal in the colon, even though the patient is having frequent bloody discharges from the rectum

The roentgen findings are quite characteristic At first colonic irritability and spasms occur, followed by disappearance of haustra-

tions when the edema and induration cause thickening of the bowel wall The bloody, mucus-coated mucosa produces the fuzzy outline seen in the films, and later, sloughs produce a ragged outline Progressive developments produce a general shortening of the colon, a gradual decrease in the size of the lumen, and evidences of kinks, adhesions, walled-off perforations, or obstruction Repeated roentgenographic studies during the course of the disease should be used to register the improvement which is to be expected under adequate treatment

If the patient's condition permits, a cholecystographic study should also be made All patients should have chest films to rule out tuberculosis or any conditions which might be complicating the intestinal condition

Laboratory Studies —These data are of considerable help Blood counts, not only to determine the degree of anemia which is often extreme, but to show the eosinophilia so often present, are important Chemical studies of the blood have shown no constant findings but may show acidosis, diminished chlorides, calcium, and phosphorus, renal insufficiencies, and varying degrees of vitamin deficiency Prothrombin determinations and other coagulation tests usually show normal findings The sedimentation rate is apt to be increased Serologic tests to rule out syphilis and lymphopathia venereum, and perhaps amebiasis, agglutination tests for dysentery, typhoid, and salmonella groups, and skin tests (Frei, tuberculin) should be performed routinely

Fractional gastric analysis, using histamine as a stimulant to gastric secretion, may show variations Absence of an achlorhydria does not necessarily rule out the possibility of absorption of unchanged protein as shown by Walzer and Gray Mere so-called "gastrogenous diarrhea" never accounts for the severe symptoms of ulcerative colitis, and this is also true of pancreatic deficiences

Stool Examinations —Such studies are important and should be performed daily for at least the first ten days At first they will show blood, mucus, and mucosal shreds, with or without admixed feces Cysts or ova of parasites should be looked for, and undigested food particles should be noted Although bacteriologic studies are best carried out primarily on specimens removed through the proctoscope as previously mentioned, they may be continued on specimens of stools, thus avoiding repeated instrumentation The effect of treatment on the flora may be checked, bacteriophages may be looked for, and vaccines may be prepared The improvement in the general appearance of the stools, the disappearance of blood, and the gradual increase in consistency in cases under proper treatment is most gratifying

Allergy Study —This may be started during the period of other examinations Authorities agree that skin and passive transfer tests are of no value in determining food sensitivity but may be useful if the patient is also sensitive to pollens, dusts, or emanations Bacterial allergy is difficult to demonstrate, but removal of infected teeth or tonsils may result in prompt disappearance of the ulcerative colitis, thus suggesting sensitivity to bacteria, their products, or the products of dead tissues produced by the infection Refer to an allergy department or specialist does not answer the requirements In a condition as severe as ulcerative colitis the food causing the severe reaction must be one which is being taken daily by the patient In my experience milk has been found to be one of the offending foods in over 80 per cent of cases and the only one in nearly 40 per cent Wheat in 18 per cent, tomatoes in 15 per cent, oranges and potatoes 12 per cent each, and eggs in 9 per cent are other sources. During the general study of the case I usually eliminate milk and milk products from the diet which should be well-balanced and contain an adequate amount of residue In milk-sensitive patients there will be considerable improvement in symptoms by the time the study has been completed, and thereafter a careful record of all foods eaten and of frequency and character of bowel discharges and general symptoms will usually disclose other allergens When no improvement occurs under the milk-free diet, a more detailed study is indicated Instead of slow and often inadequate elimination diets, we have been using a diet which contains none of the foods usually eaten daily and which have been shown to be so frequent a cause of ulcerative colitis In other words we eliminate milk, eggs, wheat, potatoes, oranges and tomatoes, and their products altogether, and in order not to have too many offending foods to deal with, we give a diet consisting of only about a half dozen foods which, after careful inquiry, we find the patient has not been in the habit of taking regularly and which he has not ever suspected of causing any symptoms Such a diet is necessarily not well-balanced, is often not sufficiently nourishing, and may cause some loss of weight so that it must be emphasized that it is used for only a few days Careful individual study by the physician, intern, nurse, or other daily attendant is absolutely necessary A sample diet of this kind is our

allergy test diet number 2 consisting of five foods—gelatin, rice, rye, peas, and raspberry (or other vegetable or fruit)—and given as follows

ALLERGY TEST DIET

Breakfast boiled rice, Ry-Krisp, gelatin drink, raspberries
Lunch peas, Ry-Krisp, gelatin drink, raspberries
Supper same as lunch or breakfast
Between meals and at bedtime gelatin drink and Ry-Krisp

The gelatin drink is made by adding a teaspoonful of powdered gelatin to a fruit juice made of the fruit or berry used in the diet, sweetened and fortified with dextrose Sixty to eighty grams of gelatin and 100 to 150 Gm of dextrose can be used in this diet to supply protein and to bolster the caloric intake

If this diet contains no food to which the patient's colon is sensitized, definite improvement can be seen within two or three days Stools become a little less frequent and bloody, the patient becomes brighter and says he feels better in general, and fever may show a downward course If this improvement does not occur, it means that either the patient is allergic to one of the five foods being taken, that he is allergic to some other factor (bacteria, pollens, etc), or that the case is not one of allergic origin The very restricted allergy diet must not be kept up too long in such cases, although at times it may require five or six days to get definite improvement

When improvement occurs, new foods are added daily with careful observation for any even slight exacerbation as a result of any particular addition By repeated trial, allergens can be conclusively demonstrated In view of the fact that the six foods previously mentioned are usual offenders, they should not be tried out until the patient has achieved a maintenance diet by the addition of meats, cereals, vegetables, and fruits in considerable variety A complete study for food allergy may take from two to four weeks Finally, the patient is placed on a well-balanced diet with caloric values according to his requirements, and it is surprising to see the improvement on a diet free of offending allergens, even though the diet contains considerable quantities of so-called roughage Desensitization to offending foods by injection of food proteins or by feeding increasing quantities has not been found of value

Treatment

Although removal of the offending foods from the diet is essential and removal of focal infections may be of the greatest value in treating a patient with ulcerative colitis, there are definite indications for other therapeutic measures

General Treatment.—Rest, physical and mental, is indicated Fluids to replace those lost by the diarrhea are necessary and at first must be given parenterally Transfusions, plasma, and glucose and saline solutions with added ascorbic acid should be used to reestablish water balance and overcome the anemia Protein hydrolysates, amino acids, and albumin are of help, but in milk-sensitive patients the milk derivatives may cause untoward reactions and may aggravate the bowel lesions This may also be true of blood from a donor who has eaten food to which the patient is sensitized Vitamins, minerals, and endocrine and hormone products must be given, at first parenterally Hygienic care, fresh air, sunshine, ultraviolet radiation, and oral hygiene are imperative

Symptomatic Treatment.—In order not to disguise the effects of the allergic study this should be kept at a minimum, but in the early stages some sedatives and antispasmodics may be prescribed Coagulants may be indicated Skin and rectal conditions may require attention, preferably not surgical Gelatin enemas may help to control bleeding and allay irritation

Immunologic treatment, the use of vaccines, sera, bacteriophages, or bacterial filtrates, is of value in some cases Artificial pyrexia, very popular twenty-five years ago, is still being used and is useful in any allergic state

Specific Therapy—This is of course necessary for amebiasis, and a course of amebicidal therapy is recommended by some as a good routine procedure to rule out the possibility of unrecognized amebiasis Some authorities also recommend routine treatment with sulfonamides which are, necessarily, only of value where the colitis is specifically bacterial in origin and where there is a complicating secondary infection Antibiotics have also had their advocates but are of value only where infection plays a prominent role Whether or not the bowel content can be sterilized is of comparatively little moment in a case of allergic colitis

Psychotherapy—So popular today in a great variety of chronic illnesses, it is also strongly advocated in this disease Without doubt, the extremely ill ulcerative colitis patient requires proper psychologic, supportive care, but elaborate psychologic studies often make the patient more miserable It is remarkable how rapidly

the patient's mental attitude improves when symptoms begin to subside

Surgical Treatment.—I have not yet found an uncomplicated case which has required an operation Too many patients are being subjected to ileostomy or colectomy who should have been helped by proper medical care Certainly any operation performed during an acute severe exacerbation is too risky to be considered Even operations for hemorrhoids or fistula-in-ano may cause a fatality If, as a result of prolonged or repeated attacks, the colon has become obstructed or badly crippled as a result of scarring, fibrosis, adhesions, or extensive polypoid changes, operation must be considered Acute perforation, which may require operation unless promptly walled-off, is a very serious complication

Prognosis

Mortality in our cases treated as outlined has been under 5 per cent and then due to complications When the treatment has been faithfully carried out and the patient has been placed on a regime based on the facts learned during the study and the early treatment, some patients will not have exacerbations, but most of them will return, even as they will with asthma, hay fever, and other allergic conditions If, at the onset of an exacerbation, a careful search for the cause is instituted, it will usually be found that

1 The patient deliberately or inadvertently ate one of the foods to which he had been found to be sensitized

2 That some new sensitivity, perhaps not previously recognized, such as pollen sensitization, may have developed

3 That activity at some focus of infection, an abscessed tooth, an acute upper respiratory or acute pelvic infection, has occurred

In an intelligent patient under careful, although not necessarily close, supervision by a clinician familiar with allergic problems, the prognosis in ulcerative colitis can be said to be decidedly favorable, not only in regard to restoration of a well-functioning colon but in regard to the danger of severe exacerbations

Summary and Conclusions

1 Food allergy is the most important etiologic factor in so-called "idiopathic ulcerative colitis"

2 Pathologic changes in the colonic mucosa are identical to those seen in experimental work in intestinal allergy

3 The history and the symptoms in ulcerative colitis are explainable on an allergic basis

4 Secondary infections require specific care

5 The good effects of treatment based on the concept of allergy can be demonstrated by proctoscopic and roentgenologic studies

6 General treatment should not be neglected

7 It is important not to treat a patient for allergic ulcerative colitis until all other causes have been definitely ruled out and particularly only after carcinoma has been excluded as a cause of symptoms

88 Sixth Avenue

Discussion

John R. Paine, M D, *Buffalo*.—I do not know of any surgeon who would disagree with the statement that the primary treatment of patients with idiopathic ulcerative colitis should be medical in character On that point we are all agreed. On the other hand, I think that surgeons have a just cause for complaint to their medical colleagues when they are first consulted late in the course of this disease in a patient who is progressively getting worse despite the best and frantic efforts of his doctor Indeed, too often the surgeon is called in when the patient is scarcely more than moribund As long as this situation prevails, there can be little excuse for any dissatisfaction with the relatively high mortality rates associated with surgical treatment.

Dr Andresen has stated that he has had a mortality rate of 5 per cent or under in his patients with ulcerative colitis treated medically and that this mortality has been due to complications Inasmuch as the complications of ulcerative colitis are usually recognized as indicating surgical treatment, it would be my feeling that the mortality of patients treated solely by medical means should be zero if exception be made for those patients having a fulminating variety of the disease, which even the boldest of surgeons usually refuses to have anything to do with Yet, we surgeons might be justified in still further improving the mortality statistics of medical treatment by accepting these extremely poor risk patients and with the help of the best modern supportive treatment subject them to a one-stage ileostomy and colectomy There is little to lose in such a situation, and the results might be interesting

Permanent ileostomy with or without colectomy remains the standard surgical procedure for patients with idiopathic ulcerative colitis Considerable debate exists, however, as to when and how often these procedures are indicated Aside from the usual complications, I believe that the patient who fails to respond satisfactorily to six weeks of medical treatment or who has a remission of his disease severe enough to require hospitalization should be subjected to ileostomy I doubt if Dr Andresen would concur in this opinion It is also my opinion that few patients subjected to ileostomy should be allowed to retain their colons because of the high incidence of carcinoma that is known to exist in these

individuals Surgery is ruthless perhaps, but its goal is to "cure" the patient, whereas medical treatment, whatever its aims may be, usually achieves only "control" of the disease

I am not unmindful of the disadvantages of ileostomy or of the far-reaching, indirect but adverse effects which it may have, but I think all of us can find encouragement in the facts presented by Drs McKittrick and Moore on this subject at the meeting of the American Medical Association in Chicago in June, 1948 They reported that among 104 patients with ileostomies performed for idiopathic ulcerative colitis, 84 per cent considered themselves to be in good health, 97 per cent were working, and 67 per cent considered their social life to be satisfactory Remember that medical treatment had failed in these patients!

I am sure that all of us hope that Dr Andresen may be correct in his theory that allergy explains the cause of this condition If future experience shows that others can duplicate the excellent results that he reports from his clinic, much will have been accomplished. He must excuse us, however, if for the moment some of us remain skeptical

John J Maisel, M.D, *Buffalo*—Dr Andresen has again emphasized his ideas concerning the role of allergy in the cause of idiopathic chronic ulcerative colitis His views are quite provocative

When a clinician of such outstanding ability as Dr Andresen draws such conclusions as he has, one should be provoked into a very careful analysis of our patients along the paths which he has outlined. There is no doubt that the clinical course of many patients is unsatisfactory because of an undiscovered allergy, whether it be a primary or an aggravating factor in this disease It behooves us, therefore, to search diligently for such a condition I must admit that I have gone through several cycles in reference to allergic studies not only in ulcerative colitis but in other gastrointestinal diseases At times, chiefly under the stimulus of Dr Andresen's reports, I have stressed such investigations, only to become somewhat discouraged with my failures and consequently to neglect them However, after hearing the paper today I am once again ready to give allergy the attention which it properly deserves, and I hope that others who have had negative results will review this aspect of their work.

Allergy probably plays some role in ulcerative colitis, but it is impossible to agree with Dr Andresen's statement that "allergy is almost invariably the cause of this disease" The broadness of this statement has been and still is quite controversial In this respect I would like to comment briefly on the experimental evidence of Gray, Walzer, and Harten which Dr Andresen has cited. Although it is true that the tissue reactions which this group described are very similar to those seen in the early phase of chronic ulcerative colitis, there is one important difference, namely that the experimental changes were of a very transient character, disappearing within one hour, while those in the disease are, of course, persistent No one yet has been able to develop the lesions of the more advanced stages of ulcerative colitis by allergic reactions It requires the theoretic assumption that repeated allergic insults will, in time, produce ulceration This may be true, but it remains to be proved. Furthermore, the allergic theory implies that the colon is the selective shock organ, at least in those patients with colonic disease only It is difficult to understand why this should be so, for in experimental work the entire gastrointestinal tract reacts equally to allergic reagins Therefore, it seems as though it is very hazardous to use such a theoretic concept as a basis for the etiology of this disease without very definite clinical proof Has such proof been obtained?

If allergy were invariably the cause of chronic ulcerative colitis, it would be impossible to account for the improvement which one observes in patients who have been treated by many other methods or symptomatically only, giving no consideration to any allergic factor Yet the clinical result that one sees with such methods is, I believe, comparable to that obtained by Dr Andresen. Also fitting into this category are the patients who go into a spontaneous remission, such remissions, although not quite as characteristic of this disease as they are of peptic ulcer, are commonly observed. All of these patients are exposed to the same allergens, whether they be food, pollen, or bacteria, during their remissions, which may continue for months or even years, as they are during the active phase of the disease

Incidentally, I would point out that, in general, chronic ulcerative colitis need not be regarded too pessimistically Many, if not most, patients have the disease in a mild form which is amenable to very simple therapeutic measures I feel that the concept of the disease is somewhat colored and distorted by that group of patients who develop it in a severe form and who become our hospital and eventually our surgical problems

I want to express one more thought According to recent papers and discussions it would seem that the internists and gastroenterologists are almost ready to abdicate their duty to treat ulcerative colitis by transferring that duty to the psychiatrist I feel very definitely that the psychiatrist is needed in only a small number of cases Dr Andresen's comprehensive paper outlining the variety of therapeutic measures employed clearly shows that the treatment of this disease must remain within our fold.

Dr Andresen, *Closing*—I am much gratified that my presentation brought out such comprehensive discussion I am glad that the surgical discussant agrees with me that surgery should be confined to the complications of ulcerative colitis which produce persistent symptoms

I have seen a number of patients treated by ileostomies alone, who have had a persistence although a diminution, in colonic symptoms, and some of those with colectomies have developed ileitis which closely resembled the original ulcerative colitis Unless the cause has been found and eliminated, there will be persistence or recurrences even after operation No definite period of so-called "medical treatment' can be postulated as

being of the proper duration to effect a satisfactory result It depends on the type of treatment used

The search for an allergic cause for the disease is often discouraging and takes a great deal of patience on the part of patient and physician Not all patients can be persuaded to go through such a study but prefer operation, crippling and unsatisfactory as it is Comparing ulcerative colitis with allergic manifestations elsewhere, as in the respiratory tract, discloses many similarities Allergic reactions may occur in the whole gastrointestinal tract or in the whole respiratory tract at one time or may occur in only parts of them, as in the stomach or colon or in the nose or bronchi Repeated mild allergic insults will result in no organic changes, but continued reactions will have an effect in both tracts Seasonal occurrences and spontaneous remissions are common to both, and only careful study will reveal the reason for them Asthma may be due to food allergy, ulcerative colitis to pollen allergy That ulcerative colitis can be caused by allergy is not a theory It is a fact that can be testified to by anyone who has seen through the proctoscope the entire disappearance of lesions upon withdrawal of an allergen and their reappearance upon its resumption

CURE FOR UNDULANT FEVER

Two Northwestern University physicians reported this week that BAL (British Anti-Lewisite) may become an effective weapon against undulant fever Their experiments show that the compound kills the disease microbes in test tubes

Dr Harry B Harding, associate professor of bacteriology, and Dr Gordon W Raleigh, on the staff of the department of medicine, both of the Medical School faculty, told results of test-tube research with the drug before a recent meeting of the Evanston Hospital Alumni Association

Animal studies are now under way to determine whether BAL, originally developed as an antidote for Lewisite, a poisonous arsenic gas, may be employed as a cure for undulant fever (brucellosis) in humans

In their research, Drs Harding and Raleigh first grew the disease microbes in culture tubes at body temperature for forty-eight hours A row of sterile broth tubes then was set up and BAL added in minute amounts The first tube in the series received the largest amount of the drug, and the others proportionately less, with the last tube receiving the least Then a standard amount of brucellosis culture was added to all tubes, which then were incubated for a number of days

In this way, the smallest amount of the drug which would completely inhibit growth of the microbes was determined According to the researchers, in order to be practical the BAL must be active in such small amounts that it will kill bacterial organisms without harming the undulant fever patient. It is one thing to kill bacteria in experiments, and quite another to avoid overdoses in therapy on humans

Undulant fever is widely prevalent in American rural areas and among urban slaughterhouse workers. Aside from handlers of raw meat of cattle, goats, and swine others contract the disease from the drinking of unpasteurized milk from cows infected with Bang's disease, the bovine strain of the disease

A debilitating ailment, undulant fever causes alternating sustained fever and periods of great weakness in its acute form In its chronic phase, it resembles neuroses, among other manifestations. For example, the patient chronically afflicted with brucellosis experiences depression moods, lack of appetite, and diminished interest in his surroundings

TREATMENT OF PAPILLARY ADENOMAS OF THE RECTUM

GEORGE E BINKLEY, M B (TOR), DOUGLAS A SUNDERLAND, M D , and CHARLES J MILLER, M D , New York City

(*From the Memorial Hospital*)

PAPILLARY adenomas are frequently encountered in elderly patients This type of new growth in the past has not received sufficient consideration. Large papillary adenomas are described as villous tumors, but there is practically no mention in the literature of small lesions In recent years this type of tumor has been recognized more frequently and now comprises an important group of rectal tumors

Papillary adenomas are usually confined to the rectum Occasionally, one is situated above the rectosigmoidal junction Early lesions resemble irregular-shaped, elevated areas of hyperplasia The small tumors, when first discovered, are seldom less than 2 cm in diameter, but recurrent tumors of a much smaller size are often seen Large tumors may be 12 0 or more cm in diameter and involve as much as three fourths of the total surface of the rectal mucosa The clinical appearance, as viewed through the proctoscope, is that of a large, irregular-shaped, sessile polyp with a lobulated or papillary surface Occasionally, villi are visible without magnification Benign papillary adenomas are soft, and many are difficult to recognize by palpation The early symptoms consist of the passage of occasional small amounts of blood, an increased amount of mucus and slight change in the normal bowel habits Bleeding becomes more marked with enlargement and also with the onset of malignant change Large tumors secrete a large amount of mucus, which produces tenesmus and morning diarrhea Bulky, semistenosing tumors of the upper rectum and sigmoid often cause varying degrees of intestinal obstruction.

Treatment of papillary adenomas is an interesting problem because of the numerous variable factors associated with the disease The chief factors to be considered in the selection of treatment are (1) the benign and malignant qualities of the tumor cells, (2) the size of the tumor and its location within the rectum, and (3) age, general condition, and mental outlook of the patient

The benign and malignant qualities are of paramount importance in the outlining of appropriate treatment and in predicting the prognosis Papillary adenomas in the beginning are nonmalignant tumors A large number, however, undergo malignant change if not completely removed Papillary adenomas, in accordance with their histologic appearance, may be separated into the following groups (1) benign or nonmalignant tumors, (2) benign tumors that contain islands of cells that show atypical but not definite malignant change, (3) benign lesions that contain islands of adenocarcinoma, and (4) tumors containing invasive carcinoma in which small areas of nonmalignant papillary adenomatous tissue still remain

Atypical and malignant changes may occur at the surface, near the center, or at the base of the tumor Oftentimes, malignant qualities can be predicted to a rather accurate degree by the clinical features Purely nonmalignant lesions seldom bleed Atypical lesions bleed slightly on trauma, while bleeding of an annoying degree is encountered with malignant tumors Nonmalignant growths are uniformly soft, while those possessing cancer cells have areas of induration which are usually recognizable on palpation with the finger or palpation with the proctoscope There may be some cases of invasive cancer without recognizable induration Repeated proctoscopic examinations and repeated biopsies afford a preliminary working classification for the outlining of treatment Final determination as to benign and malignant qualities rests with the well-trained pathologist who has received the whole tumor for histologic examination.

The above fact is well demonstrated in a review of our cases The first biopsy study suggested that 58 per cent of the lesions were benign, atypical change was noted in 26 per cent, while 16 per cent revealed definite rectal cancer Repeated biopsies or examination of the whole tumor revealed that only 10 per cent of the cases remained purely nonmalignant, 28 per cent of the others did not advance beyond the atypical stage, while cancer of either large or small areas was demonstrated at the time of removal or during the follow-up period, which extended over many years in 62 per cent of cases

The size of the tumor and its location within the rectum are other factors which influence treatment Papillary adenomas may be divided according to size into small and large tumors, the small measuring less than 4 cm and the large

Presented at the 143rd Annual Meeting of the Medical Society of the State of New York Buffalo Section on Gastroenterology and Proctology May 4 1949

variety, which constituted 72 per cent of this group, measuring more than 4 cm in diameter The majority of nonmalignant papillary adenomas can be treated through the anal canal Inaccessible locations are the upper rectosigmoidal area and upper surface of the rectal valves Small, accessible, nonmalignant polyps are most suitable for local removal Inaccessible lesions and those that have attained a very large size may require radical resection

The age and general condition of the patient may at times influence treatment The average age of this series was sixty-one years Papillary adenomas are found in old and debilitated patients who are unable to withstand appropriate radical procedure Other patients due to age and mental attitude may refuse treatment unless it is of a minor nature Palliative measures may be used to advantage under the above circumstances

Treatment may be classified as radical or conservative Conservative treatment usually indicates local removal with preservation of the rectum and sphincter control Radical treatment consists of some type of segmental surgical resection of the primary lesions with or without continuity of bowel and sphincter control Local removal may be carried out by one of the following technics (1) electric cautery snare, (2) snare removal followed by fulguration of unremoved tissue, (3) local excision by means of an electric cautery knife, and (4) surgical excision and ligation of the base

The majority of small, nonmalignant-appearing tumors can be removed by the electric snare technic This type of removal preserves the whole tumor for histologic examination and permits a definite appraisal of malignant qualities Having accomplished what appears to be a complete removal of the tumor, the surgeon closely observes the healing of the rectal wound in order to determine the final results Wounds that heal without undue induration are considered satisfactory The local disease with such healing in all probability has been completely removed Careful follow-up examinations are necessary in every case.

The real difficulty in obtaining complete local removal with a snare occurs in the group of large tumors The snare is capable of removing the redundant polypoid part of the tumor, but it is often impossible to remove all papillary tissue from a large sessile base The papillary tissue that remains after cautery snare removal in a number of cases may be destroyed by fulguration or dessication Fulguration, to be successful, must be carried to the degree of devitalizing all papillary tissue above the circular muscle fibers of the rectum Snare removal, followed by fulguration, if unsuccessful in eradicating the disease, must be considered only the first step of treatment Snare removal preserves the majority of the tissue for histologic study Further treatment may consist of another attempt by conservative methods or resorting at once to surgical dissection Incomplete removal, in which the examination of the tissue reveals invasive cancer, must be followed by radical surgery The disease must be eradicated by one method or another in a comparatively short time, regardless of the pathologic report Non malignant tumors should never be allowed to become cancerous, nor an early cancerous lesion permitted to disseminate by the lymphatic and blood streams

Dissection of the tumor base from the circular fibers of the rectum by means of a flat electrode has been employed in a few cases This technic has been undertaken in an attempt to obtain more thorough removal of large, irregular-shaped polyps A coagulating current permits the operator to dissect the tumor base from its attachments under direct vision and without bleeding Preliminary results encourage the continuation of this method in the large, irregular-shaped, low lying, accessible, nonmalignant tumors

Local excision has proved to be the method of choice in a small group of large tumors located in the lower rectum This technic is suitable for polyps that can be prolapsed through a relaxed anal canal Under anesthesia, the tumor is drawn through the anus beyond the external sphincter muscle The rectal mucosa or the section of rectal wall which forms a pedicle when traction is applied is clamped and the tissue proximal to the clamp ligated with interrupted mattress sutures The tumor is removed with a scalpel and the prolapsed rectum replaced This operation affords a wide local excision and has been followed by gratifying results in a small number of cases

Some type of segmental resection is the treatment of choice for malignant and atypical papillary adenomas and also for nonmalignant tumors which cannot be eradicated by conservative methods The most radical forms of rectal surgery are necessary for the invasive types of malignant papillary adenomas The operation of choice consists of the one-stage abdominoperineal resection for tumors located in the lower rectum Segmental resection with end-to-end anastomosis may be employed for a number of lesions of the lower sigmoid and rectosigmoidal junction Wide local resection of the bowel and excision of the lymphatic drained areas is advisable in all malignant cases

Our present knowledge of the behavior of atypical papillary adenomas indicates that this type

of disease can no longer be treated as an innocent nonmalignant tumor. Treatment in the past has been too conservative Many recurrences have followed the previously described type of local removal It now appears that in order to salvage the highest percentage of cases in this group, the tumor-bearing area will need to be completely removed in a surgical fashion This removal may be accomplished by a proctosigmoidectomy Five cases have been treated in this fashion The operation affords continuity of bowel but is not always followed by satisfactory sphincter control Segmental resections with end-to-end anastomosis are suitable for a number of lesions in the upper rectum Further experience, with different types of surgical removal and careful follow-up, will in time suggest the type of surgery most suitable for removing atypical papillary adenomas

Radical rectal surgery, even in the elderly group, can be performed with a very low operative mortality Present day improved surgical technic, accompanied by improved pre- and postoperative care, when combined with the use of antibiotics, greatly lessens the dangers of major surgery Antibiotics have proved to be of great value in preventing serious infections in elderly people Simplified technic in the care of the abdominal colostomy has lessened the objectionable features of this artificial condition

Radiation therapy has but a limited place in the treatment of papillary adenomas These polyps are comparatively radiosensitive Our best results with the use of the physical agents have been in the large, irregular-shaped, nonmalignant group of tumors which were not completely removed by snare and fulguration This type of application consists of external high voltage roentgen rays, surface applications of radium administered by special applicators, and, in a few instances, the insertion of gold-filtered radon seeds High-voltage roentgen rays and surface applications of radium seem most useful Irradiation of the malignant variety produces growth restraint but will not eradicate the disease unless very heavy dosages are employed Large dosages of radium are not well tolerated by the majority of elderly patients Moderate repeated dosages of roentgen rays and radium rays in the form of local applicators, combined with snare removal and superficial fulguration, have produced palliative results Symptoms were lessened and the patients made quite comfortable Palliative treatment should be limited to those patients who are unable to withstand curative treatment or who refuse operation.

Cases treated from 1922 through 1943 have been analyzed in an effort to determine the final results and improve future treatment This group consists of 51 patients Twenty-two patients died as a result of or with cancer of the rectum Four died of other causes with residual benign disease Five who had complete eradication died of intercurrent disease Two are alive and well with residual benign disease Three, who are lost to follow-up, were free of polyps when last examined Fifteen other patients have survived the five years or more without recurrence

These results, although not satisfactory, are very interesting and instructive During the period under consideration, papillary adenomas were thought to be nonmalignant and rarely to develop into active rectal cancer On this assumption, treatment was of a palliative nature, often directed in the case of large tumors toward relief of symptoms rather than complete eradication of the polyp These results also serve to emphasize further the importance of selective treatment in accordance with the benign, atypical, and malignant qualities of the tumor By a better selection of cases and more appropriate treatment, we are hoping for marked improvement in the results of treatment of papillary adenomas of the rectum

Summary and Conclusions

1 Papillary adenomas occur in elderly patients, the average age being sixty-one years

2 Tumors, at the time of recognition, may be benign, atypical, or malignant

3 There is a marked tendency for benign and atypical tumors to undergo malignant change if not completely removed

4 Selective methods are preferable to any routine procedure Treatment consists of one of several types of local removal and radical bowel resection

5 Benign forms of the disease should be eradicated in a comparatively short period of time

6 Atypical papillary adenomas can no longer be considered innocent, nonmalignant forms of disease

7 Radical surgery is advisable for malignant and atypical tumors and for the large, nonmalignant tumors that cannot be removed by conservative methods

121 East 60th Street

Discussion

Sidney A Gladstone, M D, *New York City* — The presentation of Dr Binkley and his associates represents a continuation of their previously reported detailed and informative study of the clinical

and morphologic features of 48 cases of papillary adenoma of the large bowel Three points appear important first, the long duration of the disease, second, the tendency of almost two thirds of these cases to become malignant, and third, the importance of microscopic examination for evaluating the degree of malignancy and for guidance with respect to treatment

In connection with the microscopic examination of mucosal and ulcerating lesions of the rectum and rectosigmoid we have been using the method of sponge biopsy for about one year In a series of 15 cases of rectal cancer we have encountered two in which the surgical biopsy has been negative and the sponge biopsy positive The first case was that of a fifty-two-year-old white man who was admitted to the New York Polyclinic Hospital and proctoscoped because of a history of rectal bleeding The proctologist saw an ulcerating lesion and excised a piece of tissue for biopsy The resident, who had previously learned about sponge biopsy in our department, rubbed a sponge over the area and sent it along separately for microscopic examination The surgical biopsy showed a benign polyp, the sponge biopsy showed adenocarcinoma. After operation, the surgical specimen showed the presence of adenocarcinoma along with several benign polyps.

The second case was seen in the office of Dr Gorsch The patient was a thirty-eight-year-old man who gave a one-year history of diarrhea and rectal bleeding A surgical biopsy done elsewhere showed "normal rectal mucosa, muscle wall, apparently polypoid tissue" On examination Dr Gorsch saw a lesion in the rectosigmoid which appeared so friable that he preferred not to excise any significant amount of tissue because of possible perforation of the bowel wall He accordingly did a sponge biopsy On microscopic examination this showed numerous particles of tissue characteristic of adenocarcinoma of the large bowel

In both these cases sponge biopsy demonstrated the presence of a cancer previously missed by surgical biopsy It would seem that sponge biopsy has a place among the diagnostic procedures of the proctologist in the examination of accessible mucosal or ulcerating lesions.

NEW YORK STATE MEDICAL LIBRARY

Doctors of New York State are reminded of the facilities of the State Medical Library at Albany They are invited to visit, telephone, or write to the Library where a trained staff of librarians will take care of their requests

Upon request, a copy of the regulations will be sent, which lists the services of the Library, including the compiling of bibliographies, sending material on specific subjects, or filling requests for definite book or journal references

A collection of over 57,000 books and the receipt of approximately 600 current medical journals enable the Medical Library to offer a real service to the doctors of the State.

Letters may be addressed to Miss Maude E Nesbit, Librarian, New York State Medical Library, Education Building, Albany 1, New York

THE RELATION OF AMEBIC DYSENTERY TO CHRONIC ULCERATIVE COLITIS

WILLARD H BERNHOFT, M D , Buffalo, New York

THE material for this presentation is based on 105 cases of amebic dysentery which I observed and studied while serving with the armed forces in the South Pacific Diagnosis was established by finding the vegetative forms of ameba in material taken directly from the surface of the typical amebic ulcers which were found on proctosigmoidoscopic examination

After two weeks of antiamebic therapy, these patients were re-examined It was of interest to note that in 23 of the patients the entire mucosal surface had changed in appearance and did not have the characteristic ulceration of amebiasis It was markedly edematous and granular in its entirety with many petechial hemorrhagic spots, and in some there were ragged ulcerative areas which bled easily on trauma In accounting for the change, the impression was, at that time, that a secondary infection had developed in the amebic ulcers Bacteriologic studies showed no specific organisms except mixed staphylococci and streptococci There was some improvement noted, both clinically and proctoscopically, after sulfa therapy

I have been unable to establish contact with the entire 105 patients I do know, however, that two of the 23 patients, who did not respond to antiamebic therapy, have died since release from service These developed intermittent diarrhea and bloody stools with continued weight loss On the basis of the original diagnosis, their doctors placed them on very intensive antiamebic therapy without success At that time, the stool examinations were negative for both the vegetative and encysted forms of ameba The autopsy studies failed to reveal evidence of amebiasis but showed a typical picture of an acute, fulminating, nonspecific type of ulcerative colitis with perforation and generalized peritonitis

In 1947 we examined 49 patients who, according to their armed service records, had amebic dysentery while in the army and were treated for same At that time, our examinations were completely negative, despite the fact that the patients claimed frequent attacks of diarrhea These examinations included stool studies

Because many of these 49 men were having educational, domestic, and work problems, the diarrhea was considered to be of a functional nature and was treated as such Intermittent proctosigmoidoscopic examinations subsequently failed to reveal any organic pathology in any of these cases until this year At the present time, four of them are showing, in the mucosa of the rectum and pelvic colon, changes which are characteristic of ulcerative colitis Smears made from material taken from the inflammatory areas, as well as stool studies, are negative for specific organisms

Comment

In reviewing the literature I have been unable to find case reports of amebic dysentery which have followed a course similar to the two of which the autopsy studies showed a typical picture of an acute, fulminating, nonspecific type of ulcerative colitis At the present time, I am certain that 27 of the remaining 103 are alive This series is too small for statistical value, but the subject's importance makes it worthy of discussion Nineteen have had no recurrences of symptoms, five are still having nearly continuous diarrhea and have been hospitalized two to five times in four years, and three have had recurrences which responded to antiamebic therapy

It is not within the scope of this presentation to attempt further theorization as to the cause of ulcerative colitis Likewise, from the last small series of 49 cases in 1947, no definite conclusion can be made

It is my feeling that these patients had an inherent tendency toward the development of ulcerative colitis and that the previous specific inflammatory disease was the active factor in bringing about the manifestation of this tendency

Although we have presented cases of amebic dysentery here, it is my belief that patients with other specific dysentery will follow a similar course With this in mind, it behooves us to follow these cases carefully, and, when recurrences are noted, we must not assume that they have amebic dysentery nor overlook the fact that other specific dysentery may lead to an ulcerative colitis

From the replies which I have received from the original 105 cases, it is of interest to note that many have not had the benefit of proctosigmoidoscopy since they were first sent to a gastroenterologist or proctologist shortly after their release from service They have been followed by the Veterans Clinic or their family doctors who have

Presented at the 143rd Annual Meeting of the Medical Society of the State of New York Buffalo Section on Gastroenterology and Proctology May 4 1949

prescribed antiamebic therapy when their illness recurred

It is true, and I am in agreement with those who may believe that, with the government compensation received by some of the patients, there is incentive to magnify and even falsify symptoms of the disease Before drawing this conclusion with regard to any individual, he is entitled to have thorough study

When there is clinical, proctoscopic, and radiographic evidence of ulcerative colitis, one should not be misled by the original diagnosis in the management of his course of therapy It is our belief that, when medical treatment is failing, these patients should be subjected to the same surgery, namely, ileostomy and subsequent colectomy, as those who had no disease prior to the onset of their ulcerative colitis

Conclusions

I believe that patients with amebic dysentery may, even after intensive antiamebic therapy, develop a nonspecific type of ulcerative colitis which should be managed as such It is erroneous, on the basis of the original diagnosis, to continue on antiamebic therapy alone without positive proof of amebiasis or the benefit of intermittent proctosigmoidoscopy

537 Delaware Avenue

Discussion

Joseph Felsen, M D, *New York City*—Dr Bernhoft has directed attention to an important point in the therapy of chronic ulcerative colitis Do not persist in the use of amebicides in patients who have had amebiasis but who present the clinical picture of chronic ulcerative colitis He carefully refrains from drawing any conclusions as to the relationship between the two diseases This leads me to offer a few practical suggestions regarding their etiology, pathology, and differential diagnosis

Etiology—We have repeatedly noted the development of chronic ulcerative colitis in previously healthy individuals from the acute initial stage of bacillary dysentery within nine to twelve months. In the Jersey City epidemic of 1934, this occurred in 10 7 per cent of the patients This observation has since been confirmed by other investigators Bacillary dysentery and amebiasis have identical epidemiologic backgrounds, so that it is not surprising that a certain number of these patients have both infections and subsequently develop chronic ulcerative colitis The Endameba histolytica is present as a purely commensal agent, having nothing to do with the development of chronic ulcerative colitis. In tropical regions and among mental delinquents practicing coprophagy, bacillary dysentery, salmonella disease, and amebiasis may occur in the same individual. I have never seen chronic ulcerative colitis follow any disease other than acute bacillary dysentery It has taken approximately fifteen years for the opponents of this view to admit that some cases, but not all, are due to bacillary dysentery No proof of other cause has ever been offered comparable to that for bacillary dysentery To those who doubt the relationship, I suggest better recognition of the atypical forms of acute bacillary dysentery, follow up of the acute cases for one year, and careful investigation of the initial phase in patients first seen in the chronic stage

In my last series of approximately 900 patients with chronic ulcerative colitis, approximately five per cent have exhibited E histolytica. In this group, amebicide therapy has usually resulted in disappearance of the protozoan parasite but without discernible effect on the chronic ulcerative colitis.

Pathology—Amebiasis is usually limited to the colon and exhibits characteristic discrete ulcers with hemorrhagic halos and undermined edges The intervening mucosa is normal The parasites are found in the floor of the ulcer, submucosa, or submucosal lymphatics They may be demonstrated readily by crypt aspiration wet smear In chronic ulcerative colitis the mucosa is granular and usually presents linear, geographic, or serpiginous ulcers with intervening polypoid mucosa Except in the rare segmental types, no part of the mucosa is free of inflammation with infiltration by polymorphonuclear cells This may extend to or even through the muscularis Crypt aspiration wet smear invariably yields a purulent cytology in the mucosal exudate

Differential Diagnosis—Demonstration of the typical ulcers and cysts or trophozoites in amebiasis may be contrasted with the diffusely inflamed mucosa, irregular ulcers, and characteristic purulent cytology of chronic ulcerative colitis The latter also exhibits diagnostic roentgenographic findings such as lumenal stenosis, defects in mucosal pattern, and rigidity and thickening of the wall with loss of haustrations due to reparative fibrosis A purulent cytology of the mucosal exudate is an absolute contraindication to using a rectal or sigmoidal segment for re-establishing continuity following subtotal colectomy If more surgeons knew this, there would be fewer instances of infection spreading from infected rectum to healthy ileum

In conclusion, I wish to make a plea for the control of acute bacillary dysentery It is my conviction that, with successful control, we shall no longer see cases of chronic ulcerative colitis and its close relative, ileitis

RECENT ADVANCES IN ANTIBIOTIC THERAPY

SELIG STRAX, M D , and LOUIS T WRIGHT, M D , New York City

(From the Department of Surgery, Harlem Hospital)

THE discovery of penicillin and streptomycin did not lead to complacency It served as a challenge to laboratory and clinical investigators and stimulated the development of new antibiotics of microbial, vegetable, or animal origin Of the 150 substances which have been identified and described, only a few are of established clinical significance or offer promise of usefulness as systemic therapeutic agents

Aureomycin*

Aureomycin, which was discovered by Duggar and his associates of the Lederle Laboratories, is derived from a mold of the species Actinomyces—in this case Streptomyces aureofaciens [1] It exhibits remarkable versatility as an antibiotic, and studies indicate that it exerts bacteriostatic or bactericidal activity against a wide spectrum of both gram-negative and gram-positive bacteria, including penicillin-resistant and streptomycin-resistant organisms It is highly effective against most strains of rickettsia, as well as viruses of psittacosis and lymphogranuloma venereum.[2,3] On a weight basis, aureomycin appears to be less effective than penicillin against most of the coccal organisms, but it compares favorably with streptomycin against most gram-negative bacilli [4] In solution it has a low pH, and activity is reduced in an alkaline medium or in the presence of human serum. Unlike penicillin, there is no significant tendency to the development of bacterial resistance, even after months of treatment [5] The marked antibiotic effect exhibited by aureomycin against Escherichia coli and other intestinal flora as well as gram-positive bacteria indicates that it is valuable in a variety of diseases associated with the gastrointestinal tract

We have employed aureomycin with success in the preoperative preparation of patients In patients awaiting gastric surgery, aureomycin in doses of 250 to 500 mg is left in the stomach following each gastric lavage Indications are that aureomycin will apparently reduce the pathogenic bacteria of the intestinal tract more rapidly and, seemingly, as effectively as the insoluble sulfonamides, while permitting resection of small and large bowel lesions with greater safety Much additional work is needed to prove this point beyond peradventure The only unfavorable report comes from Pulaski, who used aureomycin in a series of three cases and found that 250 mg of aureomycin four times daily reduced the number of E coli in the stool but did not affect other gram-negative or gram-positive organisms [6]

An added advantage of aureomycin over other drugs or antibiotics, used in the control of peritonitis in relation to surgery of the gastrointestinal tract, is that it can be administered intravenously, and thus, high blood levels can be obtained in patients who may be gravely ill and cannot take medication by mouth or whose absorption from the gastrointestinal tract is impaired

In regional ileitis our experience is limited to two cases Both had had an ileotransverse colostomy with exclusion of the terminal ileum. Subsequent to their operation, these patients suffered recurrent attacks of diarrhea which were controlled by aureomycin One patient received 50 mg of aureomycin daily intramuscularly and the other a 250-mg capsule orally twice a day to maintain an average of two daily bowel movements

We have treated two cases of postcholecystectomy syndrome, both with chills and severe pain They have obtained satisfactory relief with aureomycin, and it is suggested that cholangitis may play as important a role in this condition as does spasm of the sphincter of Oddi The unusually high concentration of aureomycin in the bile (8 to 16 times concentration in serum) makes it particularly adaptable to the treatment of infections of the biliary system [7]

A detailed study was made of the treatment of acute peritonitis with aureomycin in 52 unselected patients at this hospital These included 35 cases of appendical peritonitis, 16 cases of perforated duodenal ulcer, and one perforated sigmoid diverticulum The over-all mortality rate was one half that of a similar group treated postoperatively in this hospital in 1946 and 1947 with penicillin, sulfadiazine, and a few cases in which streptomycin was used These results are reported in detail in a paper that is in press [8]

Since the above was submitted for publication, we have treated several additional cases of peritonitis with aureomycin with no deaths At the present time the dose schedule used in the treat-

---

Presented at the 143rd Annual Meeting of the Medical Society of the State of New York, Buffalo Section on Gastroenterology and Proctology May 4 1949

Aided by a grant from the Harlem Hospital Surgical Research Fund, Inc

* Aureomycin was supplied through the courtesy of the Lederle Laboratories Division of the American Cyanamid Company

ment of peritonitis is 500 mg of the drug dissolved in 500 cc of 5 per cent glucose in distilled water, administered as an infusion twice daily when the decision to operate is made After operation, as soon as Wangensteen suction can be safely interrupted, the aureomycin is administered in doses of 500 mg twice daily orally, and this is continued as long as is necessary

In June 1948, we treated a patient with severe pyoderma gangrenosum complicating intractable nonspecific ulcerative colitis [9] The patient had had a permanent ileostomy performed in November, 1947, with little change in the extensive ulcerating lesions of the left upper and lower extremities With small doses of aureomycin intramuscularly, the skin lesions healed rapidly, and the drainage of pus and blood from the distal ileostomy stoma and from the rectum ceased The results in the colonic condition in this case were sufficiently impressive to warrant further study of the clinical effects of aureomycin in chronic ulcerative colitis

In a preliminary report from this hospital which has been accepted for publication there is a number of "active" idiopathic ulcerative colitis cases which were treated with aureomycin with dramatic results in the cases of the so-called "active" colitis [10] In these cases, there was a noteworthy reduction of the number of daily stools and a disappearance of blood The aureomycin in these cases is used orally in a dose of from 1 to 2 Gm a day in divided doses Additional cases of ulcerative colitis, observed since this paper was prepared, confirmed our original observations and convinced us that aureomycin is a valuable drug in this condition, superior to sulfonamides and all drugs previously used In fact, we have discontinued the use of all sulfa preparations in this condition

Herrell and Heilman studied the concentrations of aureomycin in body fluids and organs [7] They conclude that aureomycin is excreted slowly and that the antibiotic remains in the blood considerably longer than most previously available antibiotic substances It traverses the blood-brain barrier and appears in the cerebrospinal fluid in therapeutic concentrations Studies on placental transmission indicate that aureomycin diffuses through the placenta and is available to the fetal circulation Likewise, diffusion occurs into the pleural fluid Aureomycin is concentrated in the biliary system and is excreted in the bile in concentrations 8 to 16 times that in the serum Large amounts of aureomycin are constantly excreted in high concentration in the urine of patients receiving this antibiotic It has also been found in the liver, kidney, spleen, and lung

The efficacy of oral administration and the safety of adequate dosage make possible the use of aureomycin to achieve prompt antibiotic effects against an unusually wide spectrum of susceptible organisms

In a group of seriously ill infants at Sydenham Hospital in Baltimore, several patients with staphylococcal pneumonia and septicemia failed to respond to penicillin, yet yielded promptly to aureomycin [11] Aureomycin was used successfully in cases of Streptococcus fecalis endocarditis, pneumococcus meningitis, and influenzal B meningitis

In a study of primary atypical pneumonia, Schoenbach reports prompt remission within twenty-four to seventy-two hours [12] All cases in the series had positive tests with Streptococcus MG agglutinins and cold agglutinins

Aureomycin has been used successfully in the treatment of lymphogranuloma venereum, granuloma inguinale, lues, and psittacosis [2,3,13,14]

Aureomycin is the drug of choice in serious urinary infections In therapeutic doses, it appears in the urine in concentrations of 50 to 250 micrograms per cc [7] Schoenbach reports several cases of Coli aerogenes and Streptococcus fecalis pyelonephritis which failed to respond to penicillin, streptomycin, and sulfadiazine-thiazole but yielded to aureomycin [11] Aureomycin is probably superior to chloromycetin because the latter may permit the growth of gram-positive organisms which are frequent secondary invaders

Aureomycin is usually given in doses of 500 mg (2 capsules) every six hours the first day A maintenance dose of 250 mg every six hours may then be given over prolonged periods In seriously ill patients and in those who cannot swallow capsules, it may be administered intravenously, in doses of 200 to 1,000 mg dissolved in 500 cc of 5 per cent glucose in distilled water in one hour Because of the acidity of aureomycin, intramuscular injections are irritating

Aureomycin is remarkably nontoxic, whether given parenterally or orally [4,15] The only manifestations of intolerance have been occasional nausea and mild diarrhea The nausea is frequently relieved by the addition of aluminum hydroxide, and the diarrhea has never been of clinical significance As yet, allergic reactions to aureomycin have not been reported Aureomycin has been given to some patients for weeks or months with no toxicity noted

Chloromycetin

Chloromycetin was isolated by Ehrlich and his coworkers at the Parke-Davis Laboratories from a mold isolated by Burkholder of the Osborn Botanical Laboratory, Yale University, from field soil collected in Venezuela [16] The mold has been named Streptomyces venezuelae, the

crystalline antibiotic isolated from the filtrate of this mold has been named chloromycetin in recognition of its source and high content of nonionic chlorine which characterizes the molecule It can be prepared synthetically

Laboratory studies indicate that chloromycetin inhibits the growth of some pathogenic bacteria in high dilutions, particularly Escherichia coli, Klebsiella pneumoniae, Proteus organisms, Salmonella schottmuelleri, and Shigella paradysenteriae.[16]

In contrast to aureomycin, chloromycetin is a neutral compound In distilled water it withstands boiling for five hours Although relatively insoluble in water, it is well absorbed from the gastrointestinal tract After a single oral dose appreciable amounts of the drug are demonstrated in the blood and urine within from thirty minutes to eight hours [17] With repeated dosage effective blood concentrations may be sustained

At the present time clinical reports on chloromycetin are limited to its use in typhoid fever, epidemic typhus, scrub typhus, and Rocky Mountain spotted fever Experimental studies among other bacterial and viral infections, including atypical pneumonia, psittacosis, and lymphogranuloma venereum, indicate the possibility of adapting these findings to clinical use [18]

Woodward has treated 21 cases of typhoid fever, ten of these in Malaya [19] In all cases temperatures became normal, and blood cultures sterile for E typhosa within five days, most of them within twenty-four hours Five of these cases relapsed, and the recurrent infections responded promptly to a second course of chloromycetin. Woodward also treated several cases of typhoid fever with aureomycin with prompt sterilization of the blood but a slower defervescence The response to chloromycetin is judged to be more dramatic and more lasting

In the treatment of rickettsial diseases aureomycin and chloromycetin present almost identical results and are equally effective Schoenbach believes that rickettsia grow in the tissues impairing oxygenation of cells [11] The paranitrophenyl group in chloromycetin protects the cell from the rickettsia rather than having a direct affect on the rickettsia

Numerous cases of epidemic typhus, scrub typhus, Rocky Mountain spotted fever, and Q fever have been treated with aureomycin or chloromycetin with a return of temperature to normal within forty-eight hours The rash disappears rapidly, and the Weil-Felix reaction and complement fixation tests rise during the convalescent period, frequently after the patient is discharged Complications, such as pneumonia, myocarditis, and parotitis, are rarely seen All investigators are agreed that both aureomycin and chloromycetin are much more effective and dramatic in the treatment of rickettsial diseases than is para-aminobenzoic acid

In two series of patients with epidemic typhus symptoms regressed completely within three to five days, many within thirty-six hours of the commencement of chloromycetin therapy [20 21] Several desperately ill patients responded dramatically

In 25 cases of scrub typhus recovery was also complete in all cases with temperature returning to normal in an average of thirty-one hours after beginning of treatment [22]

Pincoffs reported 15 cases of Rocky Mountain spotted fever treated successfully with chloromycetin [23] All temperatures fell to normal within three days of the commencement of treatment

In the treatment of brucellosis with positive blood cultures for Brucella abortus, suis, or melitensis, treatment with aureomycin or chloromycetin is equally effective and vastly superior to the combined streptomycin and sulfadiazine treatment

Aureomycin has been found to be superior to chloromycetin in the treatment of tularemia

Chloromycetin is given in doses of 50 mg per Kg the first day, then 0 5 Gm every four hours thereafter Because of its low solubility, propylene glycol has been used as a menstruum for parenteral administration The diluent has produced anemia, not attributable to chloromycetin, and parenteral use is not advised at this time

Chloromycetin is well tolerated when given orally, and occasional vomiting is the only toxic symptom noted All reports up to this time deal with the use of chloromycetin over relatively short periods of one to two weeks Whether more prolonged use will provoke toxic symptoms is as yet unknown [22] The use of chloromycetin parenterally is not advised at this time Because of its low water solubility, the diluent used has been propylene glycol, and this has produced anemia in animal experiments

Polymyxin

Polymyxin is a polypeptid derived from Bacillus polymyxa and is remarkably effective against a variety of gram-negative organisms It was discovered simultaneously in America and in England, and types A, B, C, and D have been described Schoenbach believes that polymyxin is much more effective than streptomycin against gram-negative organisms, especially in delayed treatment [24] The dosage is 0 8 mg per Kg of body weight every six hours Two thirds of the ingested dose is excreted in the urine within twenty-four hours Some patients show proteinuria, oliguria, a fall and fixation of specific gravity, and tubular casts in the urine during pro-

longed treatment with polymyxin Several cases of serious infection with Pseudomonas aeruginosa (pyocyaneus), Aerobacter aerogenes, Brucella abortus, and Hemophilus pertussis (patients under one year of age) were treated successfully with polymyxin The drug is so toxic, however, that benefits are difficult to evaluate, and it has not been released for general use

Other Antibiotics

Other antibiotics which have aroused considerable interest include streptothricin, now in discard because of its residual toxic effects, bacitracin, and tyrothricin, whose use is confined to local or topical therapy because of systemic toxicity (nephrotoxic) Bacitracin was isolated in 1945 by Meleney from a strain of B subtilis In concentration of 500 units per cc in sterile isotonic sodium chloride solution or in ointment of similar potency, it may be used successfully in the treatment of superficial pyogenic lesions and ulcers and dermatologic lesions For local infiltration in the treatment of carbuncles, the solution may be injected into the base of the lesion It is not destroyed by blood, pus, or necrotic tissue

Summary

New antibiotics have been isolated that have proved to be valuable systemic therapeutic agents The most important of these antibiotics are aureomycin and chloromycetin

In our hands aureomycin has exhibited bactericidal activity against a very wide spectrum of bacteria, rickettsiae, and viruses It has replaced penicillin and the sulfonamides in the treatment of coccal infections and has supplanted the use of streptomycin in all bacillary infections except those of the tuberculosis It is most valuable in the preoperative and postoperative sterilization of the gastrointestinal test in gastric or intestinal surgery and in the treatment of peritonitis, chronic nonspecific ulcerative colitis, and serious urinary infections

Chloromycetin is the drug of choice in the treatment of typhoid fever Chloromycetin and aureomycin are equally effective in treatment of rickettsial infections and brucellosis Chloromycetin is probably also effective in the sterilization of the gastrointestinal tract preoperatively and postoperatively

Aureomycin may be given orally or intravenously in doses averaging 250 mg every six hours Chloromycetin should be used orally only in approximately double the dosage of aureomycin

Both aureomycin and chloromycetin have exhibited no important toxic manifestations

Polymyxin is remarkably effective against gram-negative organisms but has exhibited nephrotoxic effects that have held up its release for general use

The use of bacitracin and tyrothricin is limited to the local treatment of pyogenic infections

Discussion

Erwin Neter, M D, *Buffalo*—Drs Strax and Wright have given an excellent review of the present day status of the recently introduced antibiotics and have made important observations on the efficacy of aureomycin in a variety of infections Indubitably, the great importance of the discovery of aureomycin and chloromycetin lies in the fact that they are effective against rickettsiae and the larger viruses (atypical pneumonia, psittacosis) which are closely related to the rickettsiae Unfortunately, so far as it is known at the present time, these antibiotics are ineffective against the small viruses, such as the influenza and the poliomyelitis viruses

That aureomycin reduces the number of bacteria in the gastrointestinal tract and thus aids greatly in the preparation of patients undergoing surgery has been shown From the data obtained it is evident that aureomycin is of value in the treatment of acute peritonitis and of promise in idiopathic ulcerative colitis We, too, have observed that fecal material obtained from a few patients receiving aureomycin in large doses by mouth failed to show growth on bacteriologic examination However, it should be stressed that the antibiotic was not neutralized and that the negative results may have been due to the growth-inhibitory effects of the drug present in the specimen. On the other hand, we had the opportunity to follow two patients who were suffering from Salmonella infection and who continued to harbor this pathogenic microbe in the intestine during and following the administration of both aureomycin and chloromycetin in doses up to 500 mg per Kg of body weight Similar observations have been made on typhoid carriers being treated with chloromycetin

Originally it was stated that aureomycin is ineffective against Bacillus pyocyaneus and various members of the Proteus group Very recently, however, Parks from Washington, D C , and Rutenburg and Schweinburg from Boston have shown that this antibiotic is effective against some but not all strains belonging to these species and can be used to advantage in the treatment of urinary tract infections [a b] We had the opportunity to observe a patient with chronic pyelonephritis caused by Bacillus pyocyaneous The infection was of such severity that 1 ml of urine contained more than 10,000 organisms All attempts to overcome this infection by means of sulfonamides, penicillin, streptomycin, and mandelic acid failed Administration of aureomycin had dramatic results Actually, the number of organisms was first reduced to 115 colonies per ml , and subsequent cultures have become sterile It seems possible that the drug might have been less effective had the infection been localized in some other part of the body, since the concentration of aureomycin is so much greater in the urine than elsewhere In this

connection it may be of interest to discover at what concentration aureomycin and chloromycetin are present in the various parts of the gastrointestinal tract If the concentration of the antibiotic should be lower in the large intestine, one may consider the use of the drug in such a form as to preclude its absorption from the small intestine and thus obtain higher concentration in the colon

Although but a short period of time has elapsed since the discovery of aureomycin and chloromycetin, it has become clear that these antibiotics represent powerful tools in the hitherto unsuccessful fight against certain infections Much research remains to be done to determine the relative merits of these new antibiotics and also to what extent they can be used in conjunction with other chemotherapeutic agents and antibiotic substances to obtain still better results

EVALUATE RESULTS OF SURGERY FOR HIGH BLOOD PRESSURE

A study of 100 patients who underwent sympathectomy for high blood pressure shows that five years after the operation results were favorable in only about 20 per cent, according to Kenneth A Evelyn, M D, and Stewart R Cooper, M D, Montreal, Canada, and Fred Alexander, M D, Boston, Massachusetts

In this surgery, nerves of the sympathetic nervous system, which control the organs that function unconsciously and which may produce involuntary constriction of the blood vessels and other effects, are cut.

The doctors reported on their study, made at the Massachusetts General Hospital, Boston, in the June 18 issue of the *J A M A*

Five years after the operation, blood pressure was reduced to normal in 8 per cent of the patients, and significant reductions, although not to normal, were noted in an additional 13 per cent.

Results in the remaining 79 per cent were unfavorable In 52 per cent of the group, blood pressures were not significantly lower than the preoperative levels, and 27 per cent of the patients were dead

"Comparison of these results with those at the end of a two-year follow-up shows that the results of sympathectomy tend to become less favorable as the length of the follow-up period increases

"However, it seems certain that the results of sympathectomy in the most favorable cases are valuable enough to justify continued interest in methods which will improve the selection of cases and in the development of technics which will increase the effectiveness of the operation"

COLONIC DYSFUNCTION

SARA M JORDAN, M D , Boston, Massachusetts

(From the Department of Gastroenterology, Lahey Clinic)

A DISCUSSION of colonic dysfunction presupposes a well-recognized, basic understanding of colonic function Clinical precepts and practices during the past half century have reflected a complete lack of such understanding No organ of the body has been so subjected to abuse and injury as has the colon, whose finely adjusted neuromuscular mechanism and secretory apparatus have been wantonly disturbed by external interference administered under a complete misconception of the design for function provided by nature

The conception that the colon was a channel for debris—a cloaca, a sewer which had to be cleansed as far as it is possible to cleanse a sewer—has pervaded the minds of physician and patient, resulting in the inevitable medical slogan, "keep your bowels open," and in the anxious preoccupation of much of humanity on the regularity and completeness of the daily bowel movement and its importance to the life, health, and happiness of the individual

Laboratory research has given us many clues to the design of nature in colonic function The investigations of Cannon, Hurst, and Alvarez demonstrated that in the normal individual chyme reached the ileum in three to four hours, that the ingestion of food produced an ileocecal reflex which caused chyme to pass from the terminal ileum into the cecum, that for propulsion through the colon mass movements occur after prolonged periods of stasis, the purpose of which could only be for absorption, and that excretion of material might take from forty-eight to seventy-two hours From all these observations, the absorptive as well as the propulsive function of the colon was revealed, and it has been recently recognized that the right colon retrieves valuable fluid for the body, while the left colon by its secretion of mucus protects the mucosa from injury from material which physiologically should be semisolid

Although investigations in colonic physiology lag behind those in gastric and small intestinal physiology, there has been some recent work of interest, stimulated chiefly by an effort to reveal facts of importance in dealing with that most distressing disease of the colon—ulcerative colitis Peristaltic activity in the rabbit's colon was studied by the observation of reactions to the placing of dry scybala into the exposed descending colon [1] Antiperistaltic as well as peristaltic activity, as evidenced by blanching proximal and distal to the moving scybala, and movement of the scybala orad as well as caudad was noted The speed of the peristaltic activity was found to exceed that of the antiperistaltic activity by 4 1 Severing the spinal cord destroyed antiperistaltic activity, indicating that inhibition of antiperistaltic activity may come from central impulses, an interesting correlation of experimental to clinical observation It was also noted that in a highly irritable segment there was temporary circular muscular contraction on both sides of the scybalum with slowing of peristalsis, whereas in the normally irritable segment there is a constant distal relaxation with normal progression of peristalsis Thus, there is experimental evidence that abnormal central impulses, by removing antiperistaltic activity, derange motor function and that incoordination in the relation of the two sets of musculature in the colon causes constipation.

Other recent investigations have been directed toward study of mucosal changes in human patients under artificially applied stress situations and under the influence of chemical factors [2-4] Normal subjects have been placed under artificially produced stress conditions by placing their hands in ice water and applying a screw clamp to the head, observations being made under direct visualization of motility, vascularity and secretion in the colon A marked increase in motility, vascularity, and secretion was observed under such stress The changes in the colon were manifest only when the total bodily reaction was one of distress and were not a response to applied stimuli per se

Preliminary work in the investigation of conditions which affect the blood flow in the colon has, up to the present, consisted of perfecting a satisfactory instrument to measure changes of temperature in water contained in a closed system which has been inserted into the colon with an attached thermocouple leading to the outside [5] The research work involved in the perfection of this instrument has resulted in some observations on vascular dynamics and blood flow changes in the colon wall in animals under conditions of stress, excitement, and illness, all of which work has great promise for the better understanding of colonic dysfunction, both with and without organic colon disease

Presented by invitation at the 143rd Annual Meeting of the Medical Society of the State of New York Buffalo Section on Gastroenterology and Proctology May 5, 1949

Enzymatic activity has likewise received considerable attention in its relation to colonic function, here again chiefly for the purpose of a better understanding of the nature of ulcerative colitis There has been, however, some indication that abnormal chemical changes take place between normally secreted materials and the cells of the colon, probably a change in pH [6]

The proteolytic activity of extracts of stools of normal patients, those with irritable colon and those with diseases including ulcerative colitis, was studied Stools were emulsified with distilled water, centrifuged, and the supernatant fluid passed through a special filter to remove all bacteria and foreign agents The irritable colon substrate showed increased mucin-digesting ability but to a lesser degree than that of ulcerative colitis

The use of sympathomimetic and parasympathomimetic drugs has confirmed our knowledge of the effects of autonomic nerve stimulation on the colon The effect of autonomic ganglion block by the use of tetra-ethyl-ammonium chloride has been shown to be a marked decrease in motility, and when 200 mg was given intravenously, there was a complete inhibition of colon motility for as long as sixty-five minutes [7] Thus support is added to the theory of neurogenic origin of rhythmic intestinal contractions

These investigations sustain our clinical observations and experience with the physiology of the colon Hence, we have every reason to regard the colon with the same respect, even awe, with which we regard the artful and admirable devices by which the heart, the lungs, the kidneys, and the upper gastrointestinal tract carry out their functions We know that coordination of innervation and muscle and secretory glands is responsible for normal function and that normal function is subjectively expressed by an absence of sensation in the abdomen, except for an urge to defecation As a corollary to the respect which we should have for the neuromuscular coordination responsible for normal function, we should, of course, have misgivings about any unnecessary interference with it, a matter to which later reference will be made

The incidence of colonic dysfunction is unquestionably high A common estimate is that it occurs in about 40 to 55 per cent of all cases presenting themselves with abdominal symptoms in gastroenterologic clinics The symptomatology varies in intensity from mild to severe, and in those with severe symptoms there may even be a resulting disability The clinical importance of the conditions is, therefore, indisputable

The causative factors may be broadly classified in two groups first, the psychogenic factors of two types—either the occasional psychic disturbance, such as a sudden fright or temporary emotional crisis with resultant temporary digestive dysfunction, or the sustained pattern of psychic disorder, such as stress and strain and nervous fatigue resulting in an habitual colonic dysfunction—and second, the abuse of the colon with food, drugs, and chemical irritants Not infrequently, these factors may be so intertwined that treatment directed toward both factors is necessary

The diagnosis of colonic dysfunction is made by both negative and positive findings the former by ruling out organic disease and the latter by finding certain objective evidence of functional disorder It is essential that organic disease be ruled out for both the safety and the reassurance of the patient, the latter a necessary adjunct to therapy

Colonic dysfunction characterizes the condition whose nomenclature has included such terms as spastic colitis, mucous colitis, functional colitis, and finally the irritable or unstable colon The adjective unstable is aptly descriptive of the condition since instability of neuromuscular coordination of the colon is the basic physiologic defect Peristaltic activity may be slowed or accelerated, and neuromuscular contractions and relaxations, as well as secretions, increased or decreased in a disorganized way The orderly function of this propulsive, absorptive, and secreting organ is thus deranged to such a degree that distress symptoms replace the normal abdominal unconsciousness

These symptoms are constipation, diarrhea, distention, and distress, varying in intensity from mild discomfort to colicky pain While such distress may be localized in one of the abdominal quadrants or in the midabdomen, it is characteristically shifting in location, thus differentiated from the well-localized pain of peptic ulcer, appendicitis, cholelithiasis, or diverticulitis Both distention and distress have usually no definite time relation to food intake in their occurrence, although there is often a definite relationship of the occurrence of both these symptoms to the kind of food eaten There is also not infrequently a time relationship of onset of symptoms to bowel movement, usually with relief of symptoms following defecation

In general, the foods mentioned by patients as offending are the notoriously indigestible ones, all fried foods, pork, oily fish, and some of the vegetables and fruits which are easily digested by the normal digestive tract, e g , tomatoes, apples, grapefruit, and always melon Ice cold food and drink also precipitate symptoms There is a practically uniform listing of such foods

COLONIC DYSFUNCTION

SARA M JORDAN, M D , Boston, Massachusetts

(From the Department of Gastroenterology, Lahey Clinic)

A DISCUSSION of colonic dysfunction presupposes a well-recognized, basic understanding of colonic function Clinical precepts and practices during the past half century have reflected a complete lack of such understanding No organ of the body has been so subjected to abuse and injury as has the colon, whose finely adjusted neuromuscular mechanism and secretory apparatus have been wantonly disturbed by external interference administered under a complete misconception of the design for function provided by nature

The conception that the colon was a channel for debris—a cloaca, a sewer which had to be cleansed as far as it is possible to cleanse a sewer—has pervaded the minds of physician and patient, resulting in the inevitable medical slogan, "keep your bowels open," and in the anxious preoccupation of much of humanity on the regularity and completeness of the daily bowel movement and its importance to the life, health, and happiness of the individual

Laboratory research has given us many clues to the design of nature in colonic function The investigations of Cannon, Hurst, and Alvarez demonstrated that in the normal individual chyme reached the ileum in three to four hours, that the ingestion of food produced an ileocecal reflex which caused chyme to pass from the terminal ileum into the cecum, that for propulsion through the colon mass movements occur after prolonged periods of stasis, the purpose of which could only be for absorption, and that excretion of material might take from forty-eight to seventy-two hours From all these observations, the absorptive as well as the propulsive function of the colon was revealed, and it has been recently recognized that the right colon retrieves valuable fluid for the body, while the left colon by its secretion of mucus protects the mucosa from injury from material which physiologically should be semisolid

Although investigations in colonic physiology lag behind those in gastric and small intestinal physiology, there has been some recent work of interest, stimulated chiefly by an effort to reveal facts of importance in dealing with that most distressing disease of the colon—ulcerative colitis Peristaltic activity in the rabbit's colon was studied by the observation of reactions to the placing of dry scybala into the exposed descending colon [1] Antiperistaltic as well as peristaltic activity, as evidenced by blanching proximal and distal to the moving scybala, and movement of the scybala orad as well as caudad was noted The speed of the peristaltic activity was found to exceed that of the antiperistaltic activity by 4 1 Severing the spinal cord destroyed antiperistaltic activity, indicating that inhibition of antiperistaltic activity may come from central impulses, an interesting correlation of experimental to clinical observation. It was also noted that in a highly irritable segment there was temporary circular muscular contraction on both sides of the scybalum with slowing of peristalsis, whereas in the normally irritable segment there is a constant distal relaxation with normal progression of peristalsis Thus, there is experimental evidence that abnormal central impulses, by removing antiperistaltic activity, derange motor function and that incoordination in the relation of the two sets of musculature in the colon causes constipation.

Other recent investigations have been directed toward study of mucosal changes in human patients under artificially applied stress situations and under the influence of chemical factors [2-4] Normal subjects have been placed under artificially produced stress conditions by placing their hands in ice water and applying a screw clamp to the head, observations being made under direct visualization of motility, vascularity and secretion in the colon A marked increase in motility, vascularity, and secretion was observed under such stress The changes in the colon were manifest only when the total bodily reaction was one of distress and were not a response to applied stimuli per se

These investigations sustain our clinical observations and experience with the physiology of the colon Hence, we have every reason to regard the colon with the same respect, even awe, with which we regard the artful and admirable devices by which the heart, the lungs, the kidneys, and the upper gastrointestinal tract carry out their functions We know that coordination of innervation and muscle and secretory glands is responsible for normal function and that normal function is subjectively expressed by an absence of sensation in the abdomen, except for an urge to defecation As a corollary to the respect which we should have for the neuromuscular coordination responsible for normal function, we should, of course, have misgivings about any unnecessary interference with it, a matter to which later reference will be made

The incidence of colonic dysfunction is unquestionably high A common estimate is that it occurs in about 40 to 55 per cent of all cases presenting themselves with abdominal symptoms in gastroenterologic clinics The symptomatology varies in intensity from mild to severe, and in those with severe symptoms there may even be a resulting disability The clinical importance of the conditions is, therefore, indisputable

The causative factors may be broadly classified in two groups first, the psychogenic factors of two types—either the occasional psychic disturbance, such as a sudden fright or temporary emotional crisis with resultant temporary digestive dysfunction, or the sustained pattern of psychic disorder, such as stress and strain and nervous fatigue resulting in an habitual colonic dysfunction—and second, the abuse of the colon with food, drugs, and chemical irritants Not infrequently, these factors may be so intertwined that treatment directed toward both factors is necessary

The diagnosis of colonic dysfunction is made by both negative and positive findings the former by ruling out organic disease and the latter by finding certain objective evidence of functional disorder It is essential that organic disease be ruled out for both the safety and the reassurance of the patient, the latter a necessary adjunct to therapy

Colonic dysfunction characterizes the condition whose nomenclature has included such terms as spastic colitis, mucous colitis, functional colitis, and finally the irritable or unstable colon The adjective unstable is aptly descriptive of the condition since instability of neuromuscular coordination of the colon is the basic physiologic defect Peristaltic activity may be slowed or accelerated, and neuromuscular contractions and relaxations, as well as secretions, increased or decreased in a disorganized way The orderly function of this propulsive, absorptive, and secreting organ is thus deranged to such a degree that distress symptoms replace the normal abdominal unconsciousness

These symptoms are constipation, diarrhea, distention, and distress, varying in intensity from mild discomfort to colicky pain While such distress may be localized in one of the abdominal quadrants or in the midabdomen, it is characteristically shifting in location, thus differentiated from the well-localized pain of peptic ulcer, appendicitis, cholelithiasis, or diverticulitis Both distention and distress have usually no definite time relation to food intake in their occurrence, although there is often a definite relationship of the occurrence of both these symptoms to the kind of food eaten There is also not infrequently a time relationship of onset of symptoms to bowel movement, usually with relief of symptoms following defecation

In general, the foods mentioned by patients as offending are the notoriously indigestible ones, all fried foods, pork, oily fish, and some of the vegetables and fruits which are easily digested by the normal digestive tract, e g , tomatoes, apples, grapefruit, and always melon Ice cold food and drink also precipitate symptoms There is a practically uniform listing of such foods

by patients with irritable colon Certain patients also involuntarily ascribe distress to smoking and overindulgence in alcohol, and in this group hypermotility of the small intestine is usually observed in association with irritable colon

Constipation and diarrhea, either alone or alternately, are part of the symptomatology Cases with diarrhea are sometimes less tractable than those with constipation, although objective x-ray evidence is the same for both forms of dysfunction and not distinctive for either type

The word constipation in a patient's history must always be elucidated, since it is not infrequently used to indicate self-abuse with laxatives When a patient says he has for years required some form of laxatives, it is certain that he now has a bowel fatigue with spasm or atony, to overcome which he requires more and stronger laxatives This condition was probably initiated by injudicious and unnecessary interference with the function of the colon and not infrequently was begun on the advice of a physician during an acute or chronic illness following surgery or childbirth or as part of a routine for various types of symptoms Commercial advertising and drugstore and neighborhood advice contribute their share to this vicious cycle It is, however, noteworthy that in recent times the "mildness" of the laxative is emphasized, indicating that there is a wholesome reaction at least against the harshest form of colon abuse It is of literary interest to note also that back in the days of Chaucer, such a reaction was echoed in the following lines, spoken by Chantacleer in the Nonne Prestes Tale

And I say forthermore
That I ne set by laxatifs no store,
For thay be venemous, well know I it,
I them defye, I love them never a bit

The history of longstanding abuse must, of course, be differentiated from that of a recent change in bowel habit, which is a typical symptom of colon malignancy in 80 per cent of cases Cases with such a history require a most painstaking investigation to rule out organic disease

Dysfunction in the form of diarrhea may be congenital or acquired at an early age, in such cases it may be constant or induced at times by psychogenic or physical irritants It may also be a result of an acute enterocolitis, recurring with remissions In all cases, while by no means intractable, it is, as stated, less easily manageable than constipation

Secondary symptoms in this condition are nausea and vomiting and resultant malnutrition and, in some cases of diaphragmatic splenic flexure, palpitation and dizziness Extrasystoles are induced by distention of the splenic flexure beneath the diaphragm These symptoms are relieved with an improvement in colonic tonus and irritability

Adequate study to rule out organic disease of the digestive tract reveals positive objective evidence of colonic dysfunction The physical examination discloses in most cases of irritable colon tenderness to palpation over the course of the whole colon and often a tender, ropy sigmoid which can be rolled under the palpating fingers Digital examination often reveals anal spasm, especially in those cases with cathartic abuse Proctoscopy and sigmoidoscopy often show increased redness and glariness of the anorectosigmoidal mucosa and, at times, excessive secretion of mucus The x-ray examination shows two typical findings One is in the film showing the progress of the barium meal, taken three hours after a barium meal, in which there is considerable barium residue in the stomach with the head of the meal well on in the transverse colon or even in the descending colon or rectum The other is the evidence furnished by the barium enema examination made without preparation This lack of preparation is necessary since purging with laxatives or the irritating enema, usually prescribed as preparation for colon visualization, may produce temporary irritability in even a normal colon and painfully exaggerates the condition in an irritable colon Certain criteria of colon filling with the enema are used as normal, and deviations are considered abnormal With a standard head of pressure for the enema can (usually about 2½ to 3 feet) the time of filling is from two to four minutes from anal orifice to cecum, and during the passage of the barium the normal colon is gradually distended, showing haustral striations of such depth that the diameter of the colon varies from 2 to 3 inches in the descending portion to 4 to 5 inches in the right colon The frequency of haustrations is less in the descending than in the transverse and right colon With the filling of the colon, the patient experiences a sensation of filling which becomes a mild urgency for defecation when the entire colon is filled After the evacuation of barium, the left colon and rectum are normally well contracted, while the right colon, only slightly contracted, still contains a considerable amount of barium

Dysfunction, by these standards of normal function, is manifested by (1) excessive speed or excessive delay in the time of filling, (2) excessive width and smoothness or excessive narrowing and number of haustral markings, (3) excessive distress experienced by the patient or complete absence of sensation of filling, and (4) exaggerated or deficient emptying visualized after evacuation

The atonic redundant colon may be so wide and tortuous that the entire abdominal cavity appears to be filled with its visualized coils The pelvic colon is especially often redundant and dilated and may, when filled, occupy the left upper quadrant In other cases the splenic flexure is very high under the diaphragm (Kantor's diaphragmatic flexure), and if this type of flexure is redundant and dilated, it often pockets gas or fecal contents, producing a symptom complex of left upper quadrant distress radiating to the left flank and simulating renal disease These x-ray manifestations indicate an instability of neuromuscular coordination, resulting in excessive or deficient irritability, tonus, and contractility

Stool examination is important in ruling out organic disease—parasitic, inflammatory, or ulcerative—and also in indicating the degree of digestion and absorption accomplished by the digestive tract Since there is a relationship of colonic function to gastric function, an estimate of gastric acidity is at times of value, particularly in achlorhydria cases

The differentiation of colonic dysfunction from organic disease is made first by the study to rule out organic disease, but it must also be noted that colonic dysfunction may occur in association with organic disease Particularly is this the case in gallbladder disease and peptic ulcer, and under these circumstances neither of these conditions can be adequately treated unless the colon dysfunction is also treated It should be mentioned that recurrence of peptic ulcer is occasionally diagnosed when the actual condition is colonic dysfunction, sometimes induced by the treatment of the ulcer and particularly when magnesium and the silicates are used Moreover, the too frequently encountered failures with cholecystectomy for cholelithiasis are usually due to neglect of a concomitant colonic dysfunction which must be treated postoperatively in order to obtain complete relief of preoperative symptoms

Treatment of colonic dysfunction has as its dominant feature physiologic rest In a small group of cases where the causative factor is purely psychogenic and transitory, recognition of this fact by the physician and a clear understanding by the patient of the relationship of mind, emotions, and nervous factors to the behavior of the colon is often adequate therapy However, with sustained psychogenic factors operating as the sole cause but creating habitual dysfunction or when these psychogenic factors are combined with somatic factors such as colonic abuse, there is unquestionable need for somatic treatment Furthermore, in a large group of cases of colonic dysfunction the causative factor is entirely somatic and due to abuse of the colon with chemical or physical irritants—food difficult to digest, excessive alcohol and smoking, and most frequently cathartic abuse

The attainment of the highest degree of physiologic rest for the unstable colon is the keynote of treatment, just as it is for cardiac decompensation. This rest is necessary in degrees varying with the intensity of the symptoms For those patients who have severe abdominal distress and either obstinate constipation or diarrhea, hospitalization is not only a most rewarding measure but often an essential one The duration of hospitalization is usually from ten to fourteen days Complete bed rest and a diet beginning with the blandest types of food furnish the basic essentials of rest for the colon Frequent small feedings of easily digested and absorbed food, such as cream of wheat, milk toast, soft eggs on toast, Melba toast, tea, coffee, warm milk, junkets and custards are first given, and as symptoms subside, gradual additions are made of broiled beef, lamb and chicken, garden lettuce and celery, baked potato, and finally other easily digested vegetables and cooked fruits Orange juice diluted with hot water is the only form of uncooked fruit allowed If these additional foods cause distress, the diet of bland food is resumed and used for a little longer time Antispasmodics, belladonna or some of the synthetic products, and small doses of phenobarbital are used Supplementary vitamins are also valuable Smoking and alcohol are completely omitted Heat is used, both as hot water drunk frequently during the day, and in external application to the abdomen at regular intervals during the day No form of laxative is used, and although there are often several days without a stool, ultimately fecal material will reach the rectum Daily rectal examinations help to provide reassurance for the bowel-conscious patient, and if he is finally unable to expel material from the rectal ampulla, a warm oil retention enema is usually adequate aid toward accomplishing defecation

Colon tone is usually so improved by these procedures that, subsequently, stools begin to occur normally and the dietary increases cause no distention or discomfort

While the discharge diet excludes many foods, particularly all fried foods, pastries, ice cold foods, raw fruits, and certain vegetables, it is, nevertheless, a well-balanced, adequate diet obtainable anywhere without too much inconvenience Certain individuals find it impossible ever to vary it with impunity, while others are able to use a general diet some months or years after the treatment Patients often learn that when under special stress and strain, they must resume the more restricted diet

The oil retention enema and for emergencies a saline enema are held in reserve as needed

For patients with diarrhea, much the same routine is followed, except that it may require a much longer period of time before vegetables or cooked fruits can be added During hospitalization, all stools should be examined in these cases so that organic cause for the diarrhea can be ruled out

Supplementary vitamin therapy may be intensively used, intramuscularly or even intravenously during hospitalization In some cases estrogenic therapy or hydrochloric acid may also be necessary The caloric requirements are estimated according to the stature and weight of the patient and increased nutrition or reduction diets prescribed

For patients with these functional disturbances, there is usually an obvious need for revising habits of life The digestive system is second only to the vascular system as a victim of the turmoil which characterizes modern life, and if, as an offending factor, self-inflicted abuse is added, functional trouble must follow It is, therefore, necessary to neutralize the mad whirl of modern life by restful interludes in the day, week, month, and year Meals eaten in a serene atmosphere, with at least a short period of rest following the midday meal, are measures of great value Easing the burden of digestion by a good choice of food and regularity of meals and, for most individuals, a good schedule of exercise and rest are excellent digestive aids Moderation in alcohol and smoking, and often the complete omission of smoking, are necessary to prevent digestive derangements And finally, noninterference with a system which is as fearfully and wonderfully made as our digestive apparatus is a sine qua non of good function These facts are learned by experience, but by teaching and practicing them, we as physicians can prevent much unnecessary suffering

605 Commonwealth Avenue

Discussion

A. H Aaron, M D , *Buffalo* —In discussing Dr Jordan's presentation it will be interesting to note that many of the contributions and conclusions that she has given were proposed by her long before the experimental physiology and chemistry were done by later workers In other words, she had already premised many of these alterations in function which have since been substantiated by clinical and animal experimentation

This is a most stimulating and helpful situation for all who are working in clinical gastroenterology, as it should give one courage to support and sustain the contention of clinical observations, even though experimental information is not at hand at the time Accurate, well-founded observation based on clinical history, physical examination, and personal radiology by Dr Jordan allowed her to formulate the ideas that she has presented today

Personally, I have no difference of opinion with her contentions I believe that her titling, "Colonic Dysfunction," is a more acceptable term than irritable colon or such She has so thoroughly outlined the situation here that I shall avoid discussing it and devote my time entirely to the phase that is the troublesome factor of the differential diagnosis between colonic dysfunction and organic disease

Unfortunately, here we must call upon so many accessory factors to eliminate organic disease that it becomes a tremendous expense to the patient. Amebiasis has existed endemically in this country in various degrees for a number of years Since World War II it has become the most troublesome diagnostic factor in our practice I do not agree with those writers who say we have failed to recognize the bizarre forms in which it exists I do believe that the active practitioner deprived of laboratory procedures to isolate cysts and motile ameba is justified in the therapeutic test of the administration of emetine hydrochloride 0 03, 1/2 grain hypodermically, daily for six doses without any other medication, and note carefully the results

If, as Dr Jordan has emphasized, constipation is a problem, diarrhea is a much more serious one. Fortunately for us many of the patients she has discussed have had this problem over a number of years It is the patient with the short colon history of whom one must beware, and such a case demands that the following considerations be borne in mind that in the right half of the colon the carcinomatous lesion produces late evidence of obstruction and early evidence of loss of weight and anemia This is due to the liquid content of the bowel in this portion of the colon Obstruction is late On the other hand, carcinomatous lesions involving the left half of the colon are obstructive in nature and produce these signs early with few systemic evidences

From this discussion you and I must take away with us a lesson which I hope does not bore you by repetition—that every patient with colon disturbance must have the following digital examination, sigmoidoscopic examination, examination of the stool for occult blood, and a barium enema Beware of the patient with colon symptoms and a normocytic or macrocytic, hypochromic type of anemia. Carcinoma of the colon is the most favorable field for successful surgery in the gastrointestinal tract

It is my purpose to commend to you the excellent classification, diagnosis, and treatment that Dr Jordan has outlined and presume upon your time to call attention to the importance of the early recognition of carcinoma and the constant awareness of the possibility of amebiasis

Edwin Boros, M.D , *New York City* —In the realm of colonic disorders, there exists a most formidable and troublesome ailment—the so-called "irritable colon" To any internist or gastroenterologist the establishment of this diagnosis

bespeaks the existence of a condition which requires much effort in its handling

While at the outset the negative physical, laboratory, x ray, and sigmoidoscopic examinations may appear to subdue the importance of the symptoms at hand, the patient's lack of response to treatment soon conveys the problem which confronts one Optimism fades into doubt and frequent disappointment as the patient's complaints persist, despite every effort for their control

Those afflicted with this ailment complain of generalized abdominal soreness, accompanied, to a greater or lesser degree, by alterations of bowel motility At times a severe grade of diarrhea is experienced, at other times marked constipation and gaseousness Repeated detailed studies may yield nothing further than signs of rapid emptying of the colonic content There may be considerable delay in evacuation X-ray studies frequently demonstrate spasticity of the bowel

The condition does not seem to be particularly complicated and by all reasoning should be easy to control. A dietary routine is instituted, various antispasmodics and sedatives are resorted to, and here and there some satisfaction and encouragement becomes evident In many instances, however, the symptoms are more unyielding Disappointment ensues, often to the point of frustration Psychotherapy is then resorted to with variable success in the alteration of this pattern

It is important to recognize that an irritable bowel is a stubborn ailment, not readily controllable, and one that requires and taxes the efforts and resourcefulness of both patient and physician alike

USEFULNESS OF CONTACT LENSES IS LIMITED

Contact lenses will not take the place of spectacles in most cases in which ordinary eyeglasses give serviceable vision, according to Conrad Berens, M.D, New York City, member of the American Committee on Optics and Visual Physiology

Writing in the June 18 issue of the *Journal of the American Medical Association*, Dr Berens says

"During the last few years considerable progress in the manufacturing and fitting of contact lenses has taken place in the United States Not only are contact lenses now used for conditions which spectacle lenses will not correct, but many persons wear these lenses for cosmetic reasons, as well as for safety in certain sports and occupations

"Despite the recent avalanche of commercial advertising, contact lenses will not take the place of spectacles in most cases in which ordinary eyeglasses give serviceable vision. In these cases contact lenses may be a useful adjunct to spectacles, but they do not enable most persons to discard their glasses completely

"The largest group of aspiring contact lens wearers are those who have a psychologic aversion to wearing spectacles For such persons contact lenses may be a great boon. However, the public should not be oversold on the use of contact lenses Some manufacturers of contact lenses have misused the public vanity through advertising unwarranted claims for their products and their services"

Dr Berens bases his conclusions on an investigation of contact lenses conducted by the American Committee on Optics and Visual Physiology in which certified specialists of the American Board of Ophthalmology were queried on their experience concerning results in the fitting of contact lenses

Among complaints concerning the lenses most frequently mentioned by the 575 physicians who replied were the limited time that most patients can tolerate wearing the lenses, clouding of the solution used in wearing the lenses, and that the lenses are too expensive and many patients discard them.

The Committee recommends that the prescribing and fitting of contact lenses by technicians not properly licensed under state or national laws should be prohibited

Cases of eye injuries, eye ulcers, and loss of an eye from clumsy technic in fitting the lenses have been reported

ILEOJEJUNITIS

BURRILL B CROHN, M D , New York City

ILEOJEJUNITIS is an inflammatory granulomatous disease of the small bowel In many ways it is closely allied to or almost identical with regional or terminal ileitis, at other times the disease appears as an independent manifestation in the upper reaches of the small intestine with a clinical picture, in general, closely resembling that of regional ileitis [1]

From the standpoint of etiology, the same ignorance which pervades the field of regional ileitis can be extended to cover that of ileojejunitis Specific causative agents are unknown The age group is different from that in regional ileitis, the disease being one afflicting extreme youth with a major incidence in the second and third decades of life After the age of forty only an occasional case is seen The youthfulness of most of the cases of ileojejunitis is very striking

In the present study which covers 38 cases, there were 27 men to 11 women, a ratio of almost 3 1 This is a contrast to regional ileitis where the proportion of men to women is 5 4

The pathologic anatomy of the disease is very much like that of regional ileitis except that isolated jejunal ulcers and isolated areas of granulomatous infiltration are more likely to be noted The inflammatory lesion should be considered under four anatomic and pathologic variations which constitute its form of invasion in the upper alimentary tract (1) as a progressive invasion upward from an older regional ileitis, (2) as a diffuse primary granulomatous infiltration of the entire ileum and jejunum (rarely duodenum), (3) as a localized involvement of an isolated area of jejunum, and (4) as a combined lesion involving upper jejunum and lower ileum, the two processes being entirely discontinuous

Involvement of the Jejunum by Upward Extension from an Older Regional Ileitis —This method of extension in the ileum by widely separated skip-lesions is well known, a still greater extension upward to involve the jejunum may occur in the more severe cases of prolonged duration Such progressive involvements may take place spontaneously early or late in the course of the disease or may occur in the form of recurrences following previous resections or short-circuiting operations

Diffuse Ileojejunitis —This is the most common form and includes a group of 24 out of the total 38 cases under study Here the whole or most of the jejunum is involved either continuously or occasionally in a discontinuous manner by the appearance of "skip-lesions" with interspersed "skipped areas" of normal mucosa In two of these cases the duodenum third and fourth portions, were involved by extension as seen radiologically and as confirmed by operation Presumably, this process initially involves the whole small intestine because, when first seen, the entire small bowel may be involved in this serious granulomatous and cicatrizing enteritis

Isolated Jejunitis —Nine of the total 38 cases in this group fall into this classification This is the most interesting group since the disease involves only isolated areas of the jejunum, usually in the proximity of the fossa of Treitz The lesion may extend to involve 8 to 12 or more inches of bowel wall At other times the lower jejunum is involved with an extension into the upper ileum These incidences of isolated jejunitis have been published by Johnson, by Brewster, by Gendel and Beaver, by Lyons and Garlock [2-5] The recent literature is most interesting in so far as James has presumably published three cases of regional jejunitis with successful resections in situ This last year Husebye reported 14 cases of acute phlegmonous jejunitis as seen by x-ray or by exploratory laparotomy, the lesion being characterized roentgenographically by reduced diaphragmatic movements on one or both sides, by distended loops of small intestine, and by a mucosal relief pattern in the small bowel which was jagged with irregular circular folds and areas of segmental delay [6]

Combination of Isolated Jejunitis Plus a Localized Segment of Distal Ileitis —This was seen three times In this type the two lesions seem to be entirely independent of each other, both lesions tend to be stationary, neither process showing evidences of extension

The clinical picture of ileojejunitis differs from regional ileitis in certain characteristics The tendency to fistula formation is much less marked in the upper bowel, internal fistulas from one loop of small bowel to the other being rare, fistulas to the anterior abdominal wall are most unusual Such fistulas occur usually only as the result of the breaking down of enlarged succulent and infected mesenteric lymph nodes causing abscess formation The abscess points to the anterior abdominal wall and either spontaneously

Presented at the 143rd Annual Meeting of the Medical Society of the State of New York Buffalo Section on Gastroenterology and Proctology May 5 1949

ruptures and subsides or by its outward perforation results in an anterior abdominal wall fistula Low-grade fever frequently characterizes the chronic extended course of the disease Diarrhea is present in most of the cases but is mild Severe abdominal pain of the predefecatory type is a constant phenomenon, abdominal masses can rarely be felt Gross hemorrhage and symptoms of obstruction fortunately occur rarely the points of obstruction being usually multiple and partial, rarely singular and complete Loss of weight and secondary anemia are a constant concomitant to the disease process Nutrition is usually poor, dry skin, marked malnutrition and inanition and loss of strength characterize the severe cases Secondary sexual maturation is usually retarded because the disease so regularly is initiated in the prepubertal years of life Not infrequently, hypoproteinemia, edema of the lower extremities, enlarged palpable spleen and clubbing of the fingers denote the marked disturbance and interruption of the normal processes of absorption, metabolism, and nutrition. Serum protein may be reduced to 4 85 Gm. per 100 cc or as low as 3 8 Gm which was observed in one extreme case Loss of fat soluble vitamins and, to a lesser degree, water soluble vitamins gives rise to many deficiency manifestations Marked depression of the serum calcium may initiate symptoms of tetany Primary types of macrocytic anemia not infrequently accompany advanced instances of this disease with the color index above one and a stained smear which strongly recalls that of a macrocytic hyperchromic anemia

The roentgenographic recognition of ileojejunitis is usually fraught with little difficulty, provided the x-ray examination of the upper alimentary tract is carried out with a view to determining possible foci of granulomatous disease The roentgen appearance is that of scattered collections of barium in a small intestine which has lost its markings and its normal mucosal folds, the barium collecting in dilated areas of the lumen separated by constricted and contracted areas of disease The roentgen picture is somewhat analogous to that of sprue and often can be differentiated only with great difficulty The sacculations and the intermediate constricted areas indicate an organic rather than a functional change and suggest ileojejunitis rather than sprue The test is the ability to reverse the roentgenographic changes of sprue by means of vitamin therapy In sprue the successful use of deep injections of crude liver extract, vitamin B complex, or folic acid will cause a reversal of the changes of the mucous membrane pattern with the restoration of the mucosal folds to a normal picture Such a change cannot be produced in ileojejunitis where the characteristic roentgen picture of the disease is irreversible, even after apparent clinical cure or prolonged remission The appearance of polyps or of polypoid appearance in the mucosal pattern tend to confirm the diagnosis of ileojejunitis, since polyps do not occur in sprue pathologically or roentgenographically

The ultimate prognosis in ileojejunitis depends to a great extent upon the degree and the type of involvement of the small bowel in the granulomatous process Obviously, a localized or segmental lesion presents a different picture from the standpoint of prognosis than does a disease which involves the entire extent from ileocecal valve to duodenum In the localized forms surgical intervention, resection or short-circuiting, is feasible and usually is associated with a highly successful outcome In the diffuse processes the approach must essentially be a conservative one Fortunately, in the latter cases recession of the lesion with healing has frequently been observed In this series of 38 cases under observation the end results were noted after a follow-up of two to twelve years (Table 1)

TABLE 1.—RESULTS IN 38 CASES OF ILEOJEJUNITIS

Status of Patient	Number
Clinically well	13
Clinically fair	6
Poor with persistent symptoms	7
Died	6
No follow-up	6

It will be noted that 13 of the 38 cases were improved and free of symptoms, giving the clinical impression of being well restored to health Five of these 13 successful cases represent surgical cures by localized resections It is interesting that in the medically "cured" cases the roentgenographic evidence of disease has not changed in spite of the clinical betterment Apparently, scarring occurs in the length of the small intestine, so that even though the patients are well, with great improvement in nutrition and weight, the roentgen evidence of ileojejunitis can always be found

On the other hand, the severity of the disease is indicated by the fact that in six instances the end result was fair, seven cases were, from the standpoint of therapy, clinical failures, and six patients died Obviously the whole picture is one of either spontaneous or surgical recovery on the one hand or of chronic invalidism on the other The medical conservative treatment is aimed at attempting to overcome the infection (?) and to attain the restoration of nutrition and of weight No present known drug or antibiotic

has a specific action upon the disease The insoluble sulfa drugs such as sulfasuxidine, sulfathaladine, and sulfacetamide are all clinically used, particularly in the presence of fistulas, and at times have the seeming ability to close draining fistulous tracts As far as countering the intestinal infection or of curing the disease process, the sulfa drugs have not shown specific effects The same applies to penicillin, to streptomycin, dihydrostreptomycin, and, from a very limited experience, to aureomycin

The general health and weight of the patient is maintained by transfusions, by intravenous infusions, by a high concentrated protein diet, and by the liberal use of protein hydrolysates by mouth and by the intravenous method The intramuscular injection of crude liver extract and vitamin B complex in large amounts (2 to 5 cc) two to three times a week is a necessary measure in the presence of such a marked disturbance and deficiency of vitamin absorption from the intestinal tract

Direct indications for surgical intervention are limited to those cases in which the lesion is localized to one or more isolated segments of the small bowel

Obviously, in the first group where the disease is an extension upward from a regional or terminal ileitis, no radical surgical measure will be of any avail The same applies to the group where the whole ileum and the whole jejunum are diffusely involved Massive resection of the whole or of the major part of approximately 13 feet of ileum and jejunum has been surgically accomplished with survival of the patient and have been amply reported in the literature, but these resections were performed for conditions other than ileojejunitis [7–9] Such massive resections have not to my knowledge been adapted to the cure of diffuse ileojejunitis with survival of the patient

In the third group, those cases with high and isolated involvement of segments of the jejunum, we note the most successful of surgical procedures Here a localized resection is not only possible but gives most satisfactory results Attempts at short-circuiting alone are usually failures and frequently require resection of the diseased area of jejunum Multiple non-neoplastic granulomatous areas of involvement in the jejunum have been reported with multiple resections of the involved areas with cure [10]

The last group constitutes those cases in which a high jejunitis is associated with a distal terminal ileitis In this type two independent surgical procedures simultaneously performed are required The upper isolated lesion of the jejunum should be resected and the distal ileitis short-circuited Such unusual cases cellent results

Conclusions

The course and prognosis in ileoj varied depending on the anatomic loc the distribution of the lesion. Sp healing under medical treatment is pos the apparent restoration to good healt surgical resection where possible is satisfactory, where the lesion is diffuse gressive, the results are disappointing specific antibiotic exists for the disease p

Discussion

John Burke, M D , *Buffalo* —From experience with regional enteritis, Dr C presented another facet of this intriguing Whether the incidence of regional enteritis i in Metropolitan New York or whether t population is responsible for the large nu cases that Dr Crohn's associates see, I do n but it is obvious that Dr Crohn's exper far greater than that of anyone in our com In the last five years about 20 proved case gional enteritis have been seen in one of ou hospitals During the same period a slightl number of cases have been seen in which u ocal radiographic or operative evidence is I There have been four cases involving the j during this period, a number too small t valid conclusions In one of these cases the the incidental presence of talc-granulomat previous operative experience, and in ano lymph node removed at the time of operatic diagnosed as tuberculous All four cases hav seen within the past two years, and statemen cerning their prognosis must be guarded N them are entirely symptom free

Currently, there are three types of jej which must be distinguished by the surgeon this distinction cannot always be made witho operation and in some instances not without bi There is a jejunitis that Dr Crohn has jus scribed, second there is the phlegmon of th junum, and third the necrotizing jejunitis whic been observed in the past four or five yea Northern Germany, described recently by Fick Wolk in the *Lancet* * The phlegmonous lesion characterized by marked involvement of the mucosa, and the mucosa is rarely destroyed ex in the terminal phases The organism most c monly recovered has been the streptococcus lesion has usually been treated by resection, but entirely possible that antibiotics alone w suffice To my knowledge, this has not yet b described Fick and Wolk have described a f of necrotizing jejunitis, characterized by a very h mortality, in which there is a gangrenous invol ment of all coats of the jejunum A clostri organism resembling Clostridium welchi has b implicated in these cases In Fick and Wolk's ser of 18 cases there were 16 deaths One of the s

ıvors had been treated by resection of the involved :gment, and the treatment of the other survivor as not described. Fortunately, we have not :en this lesion in the United States as yet

I am not sure that Dr Crohn's suggestion of re-:ction for the involved jejunal segments and short-:cuting ileocolostomy for the involved ileum will : adequate in all cases It seems to me that if :struction is not present, simple by-passing an-:tamosis will not prevent the flow of intestinal :aterial through the diseased loop and consequently ıill not give it adequate rest for healing purposes

We have recently seen a case which demonstrates the failure of simple ileocolostomy The patient was a fifty-five year-old Italian man, the onset of whose disease was in 1945 For three years he was troubled with diarrhea and loss of weight and in January of 1948 developed a bladder fistula He was admitted to the Cleveland Clinic at this time in very poor physical shape At operation the bladder fistula was repaired, and presumably because of his poor condition, an ileocolostomy carried out He returned to the Clinic on several occasions during the spring and summer, but his condition was not considered adequate for resection The patient was admitted to the Veterans' Administration Hospital at Batavia, and after numerous transfusions and the use of intravenous protein hydrolysates, he was operated on in October, 1948 At this time it was seen that the ileocolostomy was in continuity In other words, the ileum had not been transected The inflammatory process of the pelvis was still quite active, and it was thought in view of his relatively poor condition that transection of the ileum at the anastomosis was the most desirable procedure, thereby defunctioning the diseased ileum The patient made an uneventful recovery, with disappearance of his diarrhea He gained about 30 pounds in weight, but in March, 1949, he again noted the appearance of a bladder fistula and was readmitted to the Veterans' Hospital The fistula was demonstrated by x-ray, although at the time of cystoscopy a definite fistulous opening could not be seen in the bladder An indurated area could be seen in the bladder wall, but no definite fistula could be seen About ten days after cystoscopy, patient was re-operated, and the defunctioned diseased ileum was resected At this time the fistula had apparently healed, because, after the ileum and sigmoid had been freed from the bladder, the bladder could be filled with fluid and no leak was seen His recovery was uneventful, and he left the hospital two weeks after operation It is obvious that at this time one cannot predict that his disease has been terminated

TECHNIC FOR LEUKEMIA

A hopeful advance in leukemia fighting was announced at the meeting of the American Medical Association in Atlantic City It consists of a precision technic for treatment that would be lost if doctors had to continue the trial and error methods of the past

A young man who about a year ago was given three days to live is now back at his work as college athletic director, thanks to the new precision technic for treatment His case and others also as dramatic were reported by Drs Charles A Doan, B K. Wiseman, and Claude-Starr Wright of Ohio State University College of Medicine

He is alive because the Ohio doctors have found that each of three modern chemicals used to treat leukemia works best in one kind of leukemia, but the one that is good medicine in one type of the disease is not good in another Aminopterin, an antivitamin chemical, for example, is effective in lymphocytic leukemia and a little effective in monocytic leukemia. But it does not help patients with myeloid leukemia That kind is helped by urethane, a chemical that is not effective in other leukemias. And nitrogen mustard, the war gas chemical, is good in monocytic leukemia, a little effective in the myeloid type, and ineffective in the lymphocytic leukemia

A patient coming to the hospital with acute leukemia is just as sick and in just as great danger as a patient with acute appendicitis, Dr Doan emphasized Vitally precious time may be lost if the doctor has to try first one treatment and then another in the hope of hitting one that is effective But study of a patient's blood cells and bone marrow will tell which type of leukemia he has and, therefore, which type of treatment will be most effective.

Diet treatment is also prescribed by the Ohio doctors for some leukemia patients on the basis of the kind of leukemia they have In one kind, the study of the blood cells shows that an enzyme chemical needed to handle fat is missing or ineffective. Such patients get a diet that completely eliminates fat. Another kind are limited to less than two ounces of protein food a day because they lack a protein-digesting enzyme

The technics the Ohio doctors have worked out resulted from the study of over 1,000 leukemia patients during the last eighteen years —*Science News Letter, June 18, 1949*

has a specific action upon the disease The insoluble sulfa drugs such as sulfasuxidine, sulfathaladine, and sulfacetamide are all clinically used, particularly in the presence of fistulas, and at times have the seeming ability to close draining fistulous tracts As far as countering the intestinal infection or of curing the disease process, the sulfa drugs have not shown specific effects The same applies to penicillin, to streptomycin, dihydrostreptomycin, and, from a very limited experience, to aureomycin

The general health and weight of the patient is maintained by transfusions, by intravenous infusions, by a high concentrated protein diet, and by the liberal use of protein hydrolysates by mouth and by the intravenous method The intramuscular injection of crude liver extract and vitamin B complex in large amounts (2 to 5 cc) two to three times a week is a necessary measure in the presence of such a marked disturbance and deficiency of vitamin absorption from the intestinal tract

Direct indications for surgical intervention are limited to those cases in which the lesion is localized to one or more isolated segments of the small bowel

Obviously, in the first group where the disease is an extension upward from a regional or terminal ileitis, no radical surgical measure will be of any avail The same applies to the group where the whole ileum and the whole jejunum are diffusely involved Massive resection of the whole or of the major part of approximately 13 feet of ileum and jejunum has been surgically accomplished with survival of the patient and have been amply reported in the literature, but these resections were performed for conditions other than ileojejunitis [7–9] Such massive resections have not to my knowledge been adapted to the cure of diffuse ileojejunitis with survival of the patient

In the third group, those cases with high and isolated involvement of segments of the jejunum, we note the most successful of surgical procedures Here a localized resection is not only possible but gives most satisfactory results Attempts at short-circuiting alone are usually failures and frequently require resection of the diseased area of jejunum Multiple non-neoplastic granulomatous areas of involvement in the jejunum have been reported with multiple resections of the involved areas with cure [10]

The last group constitutes those cases in which a high jejunitis is associated with a distal terminal ileitis In this type two independent surgical procedures simultaneously performed are required The upper isolated lesion of the jejunum should be resected and the distal ileitis short-circuited Such unusual cases give excellent results

Conclusions

The course and prognosis in ileojejunitis is varied depending on the anatomic location and the distribution of the lesion Spontaneous healing under medical treatment is possible with the apparent restoration to good health Local surgical resection where possible is eminently satisfactory, where the lesion is diffuse and progressive, the results are disappointing since no specific antibiotic exists for the disease process

Discussion

John Burke, M D, *Buffalo*—From his vast experience with regional enteritis, Dr Crohn has presented another facet of this intriguing disease. Whether the incidence of regional enteritis is greater in Metropolitan New York or whether the large population is responsible for the large number of cases that Dr Crohn's associates see, I do not know, but it is obvious that Dr Crohn's experience is far greater than that of anyone in our community In the last five years about 20 proved cases of regional enteritis have been seen in one of our larger hospitals During the same period a slightly larger number of cases have been seen in which unequivocal radiographic or operative evidence is lacking There have been four cases involving the jejunum during this period, a number too small to draw valid conclusions In one of these cases there was the incidental presence of talc-granulomata from previous operative experience, and in another a lymph node removed at the time of operation was diagnosed as tuberculous All four cases have been seen within the past two years, and statement concerning their prognosis must be guarded. None of them are entirely symptom free

Currently, there are three types of jejunitis, which must be distinguished by the surgeon, and this distinction cannot always be made without an operation and in some instances not without biopsy There is a jejunitis that Dr Crohn has just described, second there is the phlegmon of the jejunum, and third the necrotizing jejunitis which has been observed in the past four or five years in Northern Germany, described recently by Fick and Wolk in the *Lancet* * The phlegmonous lesions are characterized by marked involvement of the submucosa, and the mucosa is rarely destroyed except in the terminal phases The organism most commonly recovered has been the streptococcus The lesion has usually been treated by resection, but it is entirely possible that antibiotics alone would suffice To my knowledge, this has not yet been described Fick and Wolk have described a form of necrotizing jejunitis, characterized by a very high mortality, in which there is a gangrenous involvement of all coats of the jejunum A clostridial organism resembling Clostridium welchi has been implicated in these cases In Fick and Wolk's series of 18 cases there were 16 deaths One of the sur-

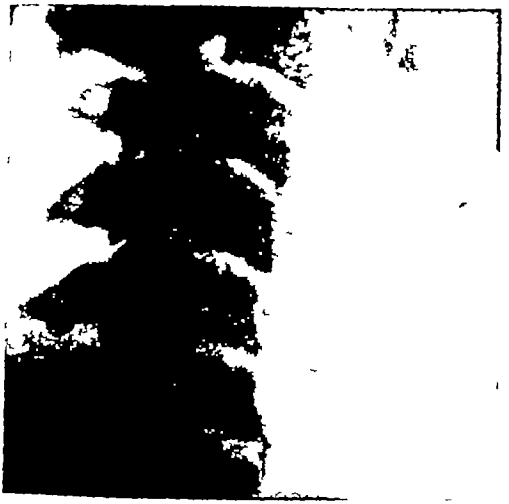

FIG 1 Marked loss of normal lordotic curve of the cervical spine with anterior displacement of the fourth vertebra due to subluxation in a forty-one-year-old woman who had suffered from migraine headache for twenty-five years and gave a history of definite previous trauma to the spine

ripheral irritation of the viscera innervated by the vagus nerve may cause reflex stimulation of the upper two cervical nerves, which in turn may carry afferent impulses to the principal cephalic sympathetic ganglia (trigeminal) via the cervical sympathetic ganglia and thus produce headache

In migraine, the upper two cervical nerves become irritated and set off a series of afferent impulses going to the cephalic ganglia via the sympathetics, which may affect any or all the cranial nerves, especially the fifth nerve, afferent impulses may also travel directly along the vagus nerve producing visceral symptoms In addition, the irritation may be conveyed to the other cervical nerves producing a diffuse clinical picture with symptoms referred for the greater part to the back of neck and upper extremity In this way, a mechanism of reflex irritation is initiated, causing headache and a wide range of symptoms which are encountered in migraine

This explanation does not in any manner disprove the findings and theory of Wolff that headache results from distention of the cranial arteries, because irritation of the upper cervical nerves can be shown to produce vasodilatation of these vessels [9]

What produces the irritation of the upper cervical nerves in migraine is the subject of much debate Trauma to the neck may cause damage to the intervertebral disks and produce a weakening or subluxation of the surrounding ligamentous struc es of the cervical vertebrae permitting the vertebrae to be thrown out of their natural alignment (Fig 1) The weakening of the ligamentous structures allows the nucleus pulposus of the intervertebral disk to herniate out of its normal position, and the herniated nucleus pulposus produces compression of the cervical nerves, which are located directly posterolateral to the intervertebral disks Traction of the head gives definite relief of symptoms in migraine, probably by making the ligaments which support the intervertebral disks taut, thus increasing the intervertebral spaces and forcing the displaced nucleus pulposus into its normal position Thus the two factors which cause pain, compression of the roots of the cervical nerves and reflex spasm of the muscles of the neck, are overcome Jostes reported definite, immediate, and often permanent relief of neck and head pain by head traction in cases which he demonstrated by the use of body section roentgenography (laminography) were due to occipitocervical lesions [10]

What produces the periodicity of attacks in migraine is difficult to say with certainty However, it has been found that in every case examined there was definite localized tenderness over the upper cervical spine on the same side as the pain, especially during the attacks and to a lesser extent (but still to an appreciable degree) between the attacks, although the patients in the majority of cases never complained about the neck This suggests the possibility that the upper cervical nerves are being constantly irritated, producing a permanent "subclinical" neuritis, even though the patient may be free from symptoms between the attacks Therefore, all that is needed to precipitate an attack is some slight stimulation of the sympathetic nervous system as occurs during emotional stress or strain, during the menstrual period in women, etc

Factors in Migraine

Trauma to the neck is probably the most important factor in producing migraine, and consequently the greater the injury to the neck, the more likely are symptoms of migraine liable to occur Sometimes, several minor injuries to the neck may produce migraine Very often, the trauma may be so slight as to be unnoticed at the time or forgotten, inasmuch as the symptoms may occur many days, months, or years later Out of 20 cases reported here, six patients gave a definite history of injury to spine prior to the onset of symptoms of migraine

The postconcussion syndrome which follows severe injuries of the skull features many symptoms which are not easily accountable to the head injury In many head injuries, even though slight, there is also damage done to the inter-

MIGRAINE HEADACHE TREATED SUCCESSFULLY BY HEAD-TRACTION MANIPULATION AND THIAMIN CHLORIDE

MURRAY M BRAAF, M D , New York City

THE fact that irritation of the roots of the cervical nerves may cause radicular or referred pain has long been recognized, but little has been known about the possibility of a herniation of the nucleus pulposus of the cervical intervertebral disk, causing pressure on the nerve roots and hence producing a radiculitis of the involved nerve roots As early as 1928, Stookey described a cervical lesion due to "ventral extradural chondroma" which was shown later by Elsberg actually to be herniated portions of nucleus pulposus [1 2] In 1943 Semmes and Murphy reported a radiculitis caused by a lateral compression of the seventh cervical nerve by a herniated and ruptured sixth cervical intervertebral disk, and Spurling and Scoville in 1944 included 12 cases in their report describing the clinical syndrome produced by compresssion of the sixth and seventh cervical roots by a lateral herniation of the nucleus pulposus [3 4] Raney and Raney last year showed that "lesion of the cervical disk is one of the commonest pathologic conditions of the cervical spine, and one of the commonest symptoms resulting therefrom is headache" [5] Kern described the effects of blocking off the nerve impulses of the cervical nerves, in 1947 he reported treatment, with favorable results, of over one hundred patients giving a history of chronic recurring headache by injecting 1 per cent solution of procaine hydrochloride into the region of the distribution of the posterior sensory divisions of the upper cervical nerves [6]

Anatomy

The cervical nerves are intimately connected and communicate with all of the cranial nerves either directly or indirectly through the sympathetic system Directly, the vagus nerve (tenth) sends communications to the roots of the first two cervical nerves, the accessory (eleventh) to the second, third and fourth nerves, and the hypoglossal (twelfth) to the first three nerves, indirectly, all cranial nerves are connected with the superior and inferior cervical ganglia of the sympathetic The cervical ganglia when traced upward join with the ganglia of the cranial nerves, these latter ganglia properly belong to the sympathetic system and may be considered to represent an upward extension of the ganglia of the paired sympathetic trunks lying alongside of the vertebral column and can be termed the "cephalic sympathetic ganglia," of which the ganglia associated with the trigeminal (fifth) nerve (the ciliary, sphenopalatine, otic, and submaxillary ganglia) represent the principal ganglia of the cephalic sympathetic system

Etiology

It must be remembered that branches of communication are as much nerves of distribution as the others Therefore, afferent stimuli originating in the upper cervical nerves may cause pain in the back of the head and neck, ear, front of neck, the shoulder, chest, and upper back through the superficial branches of the cervical plexus and the greater occipital nerve These same afferent impulses may also be carried to the principal cephalic sympathetic ganglia (trigeminal) via the superior cervical sympathetic ganglia and produce pain along the branches of the trigeminal nerve, especially the ophthalmic and maxillary branches This can be proved in patients suffering from migraine headache when the pain is situated along the back of the head and neck, as well as along the distribution of the trigeminal nerve, by cocainization of the floor of the nose on the same side as the pain. In the floor of the nose there are chiefly the nerve plexuses derived from branches of the fifth nerve, namely, the nasociliary nerve of the ophthalmic, the infraorbital nerve of the maxillary, and branches of the sphenopalatine ganglion. After twenty to thirty minutes, the pain and soreness in the back of the head and neck, as well as the pain along the distribution of the fifth nerve, will disappear Moreover, in patients complaining of pain in the lower back or even in the lower extremity, the pain can be made to vanish upon cocainization of the nerve endings of the nose on the same side [5] A reasonable explanation is that the afferent impulses which carry pain sensation from the sympathetic nervous system to the central nervous system are temporarily cut off by paralyzing the principal cephalic sympathetic ganglia

Furthermore, irritation of the first two cervical nerves may reflexly stimulate the vagus nerve and produce visceral symptoms referable to the sensory distribution of the vagus to the pharynx, esophagus, stomach, larynx, trachea, lungs, heart, and abdominal viscera, accounting for all types of chest and abdominal pain, nausea, vomiting, tachycardia, and other visceral symptoms. Pain may be referred as far down as the lower quadrant of the abdomen. Conversely, pe-

Presented at a meeting of the Society of the Alumni of Lebanon Hospital, February 8, 1949

may be typical changes of herniation of the lower cervical intervertebral disks described above (Fig 5) Consequently, these latter cases will display, in addition to migraine, radicular symptoms referable to the particular nerve roots being compressed by the lower cervical intervertebral disks However, in 25 per cent of the cases no apparent roentgenologic changes can be found

FIG 5 Marked narrowing of the fifth intervertebral disk with osteoarthritic changes of the fifth and sixth cervical vertebrae in a migrainous, forty-year-old woman who suffered also from periodic attacks of severe pain in the right upper extremity

Treatment of Migraine

Abortive Therapy—Most attacks of migraine can be easily controlled and often aborted by simple head-traction manipulation of the neck to be described below, especially if seen early during the attack It must be remembered that a neuritis of the affected nerves is set up, and the longer the attack lasts, the more pronounced is the irritation of the nerves This irritation may persist in some cases for several hours or even days after the pressure on the nerves is relieved Hence, it is an important adjunct to therapy to treat the affected inflamed nerves For this purpose, large doses of thiamin chloride of from 300 to 400 mg are injected intramuscularly during an attack after manipulation. Usually, one treatment will stop or greatly diminish the attack. However, if symptoms persist, 5 cc of 2 per cent procaine hydrochloride are injected into the upper cervical spine on the same side as the pain It is advisable, wherever possible, to have the patient lie down for one-half to one hour after the treatment

FIG 4. Marked loss of normal lordotic curve of the cervical spine, giving a so-called "poker" appearance, in a boy of eighteen who had suffered from migraine for seven years and who gave a history of previous spinal trauma

Routine Therapy—Routine therapy consists of head-traction manipulation of the neck and intramuscular injection of 100 to 300 mg of thiamin chloride It must be emphasized that continuation of therapy is of vital importance if favorable results are to be obtained Routine treatment should be carried out for at least one to two months At the start, treatments may have to be carried out daily, especially in severe cases, for the first week, then three times weekly for the next two weeks, and twice a week thereafter However, no hard and fast rule can be applied, for each case must be judged on its own merits depending upon the degree of improvement obtained.

Head traction alone may be sufficient to give relief in a good many cases, but in the chronic cases of long standing thiamin chloride must be added to the treatment

Manipulation.—Head traction is obtained by means of a Sayre's traction apparatus with the patient lying flat on his back on a hard table The advantages of having the patient lie on his back while employing head traction in preference to the standing position are twofold,

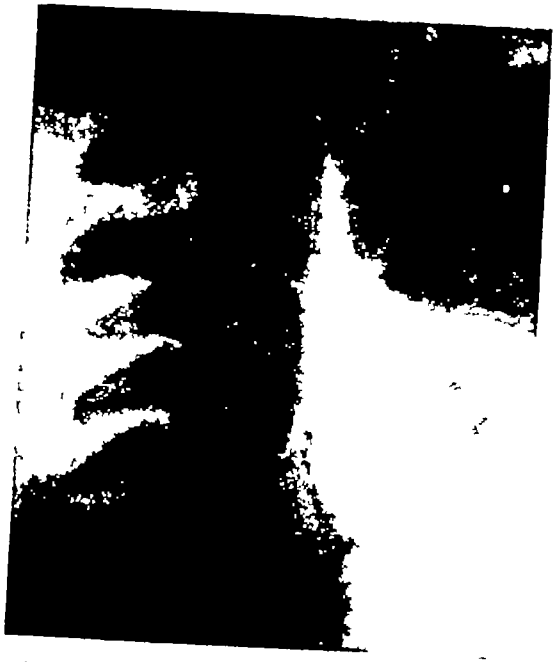

FIG 2 Anterior displacement of the fourth cervical vertebra due to subluxation with suggestive narrowing of the fifth intervertebral disk, loss of the normal lordotic curve, and osteoarthritic changes of the fifth and sixth cervical vertebrae in a thirty-six-year-old male complaining of postconcussion headaches Note similarity to Fig 1

vertebral disks of the neck (Fig 2) Of course, the more severe the head injury, the more probable is the cervical spine liable to be damaged

Constant straining of the neck in reading or looking at a moving picture usually precipitates an attack of migraine Other exciting factors are allergy, ingestion of alcohol, menstruation, emotional upsets, barometric pressure variations, severe coughing in bronchial and pneumonic conditions, prolonged strain on the neck during the administration of anesthesia for surgical operation, exposure to sun, and exposure to smoke fumes as when sitting in smoke-filled rooms All these factors are only exciting or precipitating causes producing a direct or indirect irritation of the upper cervical nerves

Heredity appears to be an underlying factor in a certain proportion of cases of migraine Out of 20 cases, five gave a family history of migraine occurring in members of the same family In these cases, roentgenologic studies of the cervical spine revealed an exaggeration of the normal lordotic curve It is very possible that cases of migraine, where there is a family diathesis, inherit a so-called "weak" cervical spine with an exaggeration of the lordotic curve which is more subject to injury after very slight trauma than a normal spine

X-Ray Findings

The roentgenographic findings characteristic of lesions of the cervical disks have been well described by many observers [11 12] They consist of narrowing of the affected intervertebral space, loss of the normal lordotic curve, osteophytic outgrowths around the affected disks, and narrowing of the intervertebral foramina These findings may be considered diagnostic of a cervical herniated disk, especially in conjunction with the clinical picture of radicular syndrome

The roentgenologic examination of the cervical spine in migraine usually shows definite variation from the normal, and the evaluation of these changes is often difficult However, for the greater part, they appear to fall into two main categories The first group shows an apparent exaggeration of the lordotic cervical curve usually seen in the heredity type of migraine (Fig 3), and the second displays a loss of the normal lordotic curve varying from slight deviation to complete reversal of the curve usually found in the traumatic type (Figs 1 and 4) In addition, there

FIG 3 Moderate exaggeration of normal lordosis of the cervical spine and minimal osteoarthritic changes at the fifth articulation in a woman, fifty-three years of age, a migraine sufferer for twenty-two years, who gave a family history of migraine

THE TREATMENT OF PARALYSIS AGITANS WITH THEPHORIN*

F M Berger, M D , Rochester, New York**

(From the Strong Memorial Hospital, University of Rochester, and the Monroe County Hospital)

THE multitude of therapeutic agents recommended in the treatment of paralysis agitans indicates that no entirely satisfactory treatment has as yet been found The therapeutic agents proposed vary considerably in their effectiveness in various forms of the disease and from patient to patient in the same group The variability in the therapeutic response poses a challenging problem to the clinician both to find the optimal combination of known drugs best suited to the individual requirements of a patient and to continue to search for new therapeutic agents of greater efficacy

The remedies which have been recommended can be divided in two groups The larger and more important of these groups comprises those drugs which possess an atropine-like action on the parasympathetic nervous system, while all the other drugs devoid of this activity fall into a chemically and pharmacologically heterogeneous group which as yet defies more detailed classification

Of the atropine-like agents scopolamine is perhaps the most widely used and most satisfactory drug The effect of this drug was known to the French neurologists, Pierre Marie, Roussey, and Souques, who were using the alkaloid during the latter half of the last century and who already had observed the striking benefit obtainable in certain cases and the symptoms of intolerance appearing in others [1] It is now known that, as a rule, scopolamine is of great benefit in postencephalitic parkinsonism, while cases from other causes are seldom affected or show intolerance to this drug Other solanaceous alkaloids such as atropine, hyoscıamine, and stramonium have been used and found to have an effectsimilar to scopolamine [2] Certain synthetic atropine substitutes such as Syntropan and Trasentine have a similar action [3 4] The analgesic drug Demerol, which is a synthetic atropine derivative, also possesses a beneficial action in certain cases [5] Parpanit and Diparcol which have been recommended as "antiparkinsonian" agents both possess atropine-like properties [6 7] The antihistaminic Benadryl which also possesses marked atropine-like action has also been found effective in certain cases of paralysis agitans [8] Of the drugs not possessing an atropine-like action only myanesin and amphetamine sulfate deserve mention [9 10]

Recently, 2-methyl-9-phenyl-2,3,4,9-tetrahydro-1-pyrıdindene hydrogen tartrate, called Thephorin, has been introduced as an antihistaminic [11 12] This substance belongs to a class of compounds which are chemically unrelated to other antihistaminics or indeed to any drug used in medicine Thephorin, in addition to its antihistaminic action, possesses atropine-like action which is about 90 times weaker than that of atropine itself when evaluated on the isolated intestinal strip stimulated with acetylcholine It differs from other agents with atropine-like properties which have been used in paralysis agitans by not having a depressant action on the central nervous system The pharmacologic properties of Thephorin suggested that it may be effective in paralysis agitans The present paper describes the results of clinical trials of the drug

Methods and Materials

We have had the opportunity to observe the effect of Thephorin on some patients whom we had previously treated by a number of other remedies with varying degrees of success Such a group of patients appeared particularly suitable for the clinical trial of a new drug, not only because of their known responses to various remedies but also because of their lower suggestibility as to the effect of new medication Of the 24 patients which have been studied nine were hospitalized and eight were able to pursue a gainful occupation, while the rest were able to take care of themselves or were looked after at home

Diagnosis —An attempt was made to determine the cause of the disease in every case which was treated The disease was considered to be of postencephalitic origin even in the absence of a history of encephalitis if the patient suffered from encephalitic residua, such as a defect of convergence, impaired pupillary reaction, or oculogyric crisis Fairly rapid

Aided by grants from the National Foundation for Infantile Paralysis Inc. and from the Committee on Therapeutic Research Council of Pharmacy and Chemistry American Medical Association.

* Thephorin is the Roche brand of phenindamine. Liberal supplies of Thephorin were made available through the courtesy of Dr Elmer L Sevringhaus of Hoffmann La Roche Inc

** Present address Wallace Laboratories Inc. New Brunswick, New Jersey

first, the patient is more relaxed and less apprehensive, and second, the position of the head can be varied, according to the angulation of the cervical curve of the spine found on x-rays, by raising or lowering the headrest on the table

With the patient lying on his back on a hard table, a Sayre's traction apparatus is placed firmly under the chin and occiput of head, and traction of the head and neck is maintained for at least five minutes This maneuver aids in relieving muscle spasm and in promoting muscle relaxation and usually gives the patient immediate relief Next, the pulley and traction bar are released and disconnected, and by using the headstraps, while the physician stands in front of the table, the head and neck are moved laterally to the right and then to the left with constant steady pull in each position for about fifteen to thirty seconds The head is then rotated toward each shoulder, while the head is still held in traction Traction should be steady, even, and constant throughout the maneuvers and should cause no pain, pain usually indicates that too much force is being used in the traction and is a sign to discontinue traction

Summary of Results

Although good results have been obtained in the postconcussion headache by head-traction manipulation, they have been purposely omitted in this report to avoid possible confusion between postconcussion headache and migraine headache

Most observers believe that several definite criteria are necessary to make a diagnosis of migraine These criteria are (1) cephalgia (usually hemicrania), (2) periodicity of attacks, (3) gastrointestinal symptoms, (4) so-called cortical or psychic disturbances such as scotoma, paresthesias, etc , and (5) relief of the attack by Gynergen or allied drugs

Twenty cases of migraine having the first two criteria and at least two out of three of the other criteria have been selected for presentation in this article They were treated by head-traction manipulation and intramuscular injections of thiamin chloride for a period varying from one to twelve weeks, the average being six weeks They included 15 women and five men, varying from eighteen to fifty-four years of age, who had had these attacks for from one to thirty-five years Those who suffered from migraine for less than five years usually responded better than the more chronic cases All the cases with the exception of two were observed for a period of six to twelve months after cessation of therapy

Evaluation of treatment is, no doubt, difficult because the results are not objectively measurable We must depend upon the statements of the patient in gauging the effects of therapy Results are based upon the frequency, intensity and duration of attacks before and after therapy However, the patient's own evaluation of improvement has been given special preference in this report, although it does not represent the true picture because the average migrainous patient is very apprehensive and tends to underestimate the amount of improvement

Each case according to the patient's statements was improved from 70 to 100 per cent, six of the 20 cases (including one case of thirty-four years duration) reported being free from attacks during the entire period, varying from six to twelve months, since cessation of therapy

Conclusions

1 Migraine is probably caused by herniations of the cervical intervertebral disks which by compression produce a neuritis (radiculitis) of the upper two cervical nerves

2 Trauma of the neck is a very important causative factor in producing migraine

3 In most head injuries there is a concurrent injury of the intervertebral disks of the neck

4 Migraine can be treated successfully by head-traction manipulation and thiamin chloride

Grateful acknowledgment is made to Dr William D Weir for his encouragement and criticism in this work

NOTE THE DATE FOR YOUR DISTRICT BRANCH MEETING—
SEE PAGE 1780

stress Restlessness and nervous tension decreased under the influence of the drug, as did the cramps and aches sometimes encountered in this disease

After the patients had been taking Thephorin for one to four months the drug was discontinued and the reaction of the patient observed In patients also taking another drug, such as one of the alkaloids or myanesin, only Thephorin was discontinued, and administration of the other agent continued in unchanged dosage On discontinuation of the Thephorin it was suggested to the patient that his condition would probably remain unchanged In spite of this a gradual reappearance of symptoms after omission of Thephorin was observed After four or five days without the drug most patients were in a similar condition as before Thephorin treatment was commenced Tremor and rigidity were intense, speech was weak and difficult to understand, movements were slower again, and the gait deteriorated All of the patients were very anxious for the recommencement of the Thephorin medication which was again able to ameliorate their symptoms

Most of these patients tolerated the drug well. Side-effects of a slight degree were observed in four Of these, two patients experienced chills and hot flushes and became slightly confused when given 50 mg three times daily Half of this dose did not cause side-effects and maintained the clinical improvement The conjunctivae of one patient became injected while he was on Thephorin Another patient experienced temporary sleeplessness when he started taking the drug, but this disappeared after a few days, although he continued taking the drug in full doses

Unfavorable Results—In 11 patients Thephorin did not have beneficial effects, but in six of these it was not given a complete trial because of the side-action of the drug Of the 11 patients who did not benefit from Thephorin six had postencephalitic parkinsonism (five of these reacted favorably to alkaloids), four suffered from idiopathic paralysis agitans (two of these being benefited by small doses of alkaloids), and one had the disease apparently as a result of carbon monoxide poisoning Side-effects of some degree appeared in nine cases They were of moderate severity in four cases, consisting of dizziness, nausea, and vomiting in two cases and sleeplessness and excitement in the other two cases These symptoms of intolerance appeared after two or three doses of the drug and disappeared promptly with the discontinuance of treatment Other side-effects complained of by the patients were diarrhea (one case), constipation (one case), sleeplessness (two cases), and nervousness (one case) Only two of the patients who did not benefit by the treatment did not show any side-effects

Discussion

One of the reasons for trying Thephorin in paralysis agitans was the atropine-like action of the drug The relief obtainable with the drug in suitable cases was, however, much greater than that observed after relatively larger doses of atropine This shows that the beneficial effect of Thephorin cannot be explained in its entirety by its atropine-like properties and suggests that the drug possesses a kind of central action independent from its atropine-like properties

The fact that Thephorin possesses both antihistaminic properties and effectiveness in paralysis agitans is of interest Benadryl, Demerol, Parpanit, and Diparcol also possess these two properties At present there is no indication that there would be any relation between the antihistaminic action and effectiveness in paralysis agitans of a substance The potent antihistaminic agent Pyribenzamine does not relieve paralysis agitans [8] Pyribenzamine does not possess atropine-like properties, and it appears that the effectiveness of certain antihistaminics in parkinsonism is more related to their atropine-like properties than to their antagonistic action to histamine

The neural mechanism underlying the manifestation of paralysis agitans is not clearly understood It appears that pathologic changes in the substantia nigra or of certain cells in the globus pallidus release certain extrapyramidal mechanisms from the restraining action of the basal ganglia These release symptoms probably originate in the reticular formation The damage in the basal ganglia manifests itself in an altered metabolism of its cells It appears that Thephorin and other drugs can temporarily influence this faulty metabolism In this connection it is of interest that the basal ganglia contain a high concentration of an enzyme that synthesizes acetylcholine [12] It may well be that in paralysis agitans the basal ganglia contain abnormally high concentrations of choline acetylase The administration of atropine or atropine-like substances will make them less sensitive to the action of acetylcholine and in this way temporarily compensate for the dysfunction of these centers The greater effectiveness of Thephorin as compared with atropine itself may be due either to a selective affinity of the drug for the basal ganglia or to a specific effect on the

onset before the fortieth year of life, various vegetative disturbances, and good response to alkaloidal treatment also favored encephalitic origin

Idiopathic or primary paralysis agitans was diagnosed when the disease developed rather insidiously after or around the fiftieth year of life The symptoms, as a rule, started unilaterally and gradually spread to the other side Pill-rolling movements of the fingers and relative preservation of mimic movements were also thought to speak in favor of primary paralysis agitans

Posology—The drug was given in doses of 25 to 50 mg two to four times daily after meals As a rule, 25 mg three times daily was tried to begin with, and the dose was increased only after it had been established that the patient tolerated the drug without serious side-effects Certain patients benefited more from 25 mg three times daily than from double this dose, while one patient needed as much as 50 mg four times daily Higher doses were not tried

If a patient was taking scopolamine, Rabellon, or another solanaceous alkaloid and was deriving benefit from the medication, this treatment was continued in full doses even after exhibition of Thephorin Similarly, patients who derived some benefit from myanesin were advised to continue with the drug at least for a time after Thephorin treatment was started *It was thought best that a patient* who was well adjusted to an alkaloid or myanesin should continue with these remedeis in full doses while a new drug was being tried

Results

Evaluation of Results—When evaluating the effect of the drug, care was taken to obtain objective evidence of improvement Charcot showed that patients suffering from paralysis agitans sometimes show spontaneous remissions which may lead to faulty conclusions during therapeutic trials [1] Remissions are usually characterized by a sudden onset and short duration As a rule, the spontaneous improvement does not last longer than a day or two and in my experience rarely longer than two weeks The symptoms of paralysis agitans may also be temporarily alleviated by suggestion, and for this reason certain patients will show improvement for a few days after the institution of any new treatment A truly effective drug will, on continued administration, maintain the improvement for several months When the medication is discontinued, a return of symptoms may be expected, and reinstitution of treatment should again abolish or ameliorate the symptoms These considerations were kept in mind when evaluating the effect of Thephorin

Favorable Responses—The treatment with Thephorin was tried in 24 patients, it was effective in 13 Of these, five suffered from postencephalitic parkinsonism and eight from idiopathic paralysis agitans The patients with postencephalitic parkinsonism had been taking scopolamine or Rabellon for some time with considerable benefit Of the eight patients suffering from idiopathic paralysis agitans who derived benefit from Thephorin, five did not tolerate or did not benefit from treatment with solanaceous drugs and were treated with Thephorin only The three other patients of this group were able to take small additional doses of scopolamine The improvement after the beginning of Thephorin administration took place after one or two days, and the full effect became apparent after one or two weeks of treatment

The improvement after Thephorin was marked in eight cases, moderate in four cases, and slight in one case The decrease of rigidity could be observed on physical examination and was also shown by the patients' ability to carry out movements and perform tasks which previously could not be carried out or were carried out only very slowly Certain patients who were not able to turn over in bed without assistance were able to do so one or two days after Thephorin medication was started Other patients were once again able to feed and dress themselves and to carry out finer movements The stooping attitude remained largely unchanged, but locomotion was greatly improved and was to a greater extent under the control of the patient It was easier for him to start and stop, the shuffle decreased but did not disappear, and automatic movements did not return The results were sometimes striking, as in the case of the man who had been confined to his chair for two years and who has been able to shuffle along once again and work as a hotel porter since he was started on Thephorin four months ago

Although in none of the patients did the natural mobility of the face reappear, the expression of the face became livelier, and the stare decreased The voice became stronger and clearer in most cases in which articulation was affected by the disease The tremor of the jaw and of the tongue often disappeared When the patient was not under nervous tension, the tremor of the limbs was also in abeyance The "readiness to shake," however, was still present and was not greatly changed by the treatment, as evidenced by the tremor exhibited by the patient when under emotional

REVIEW OF COLON SURGERY INCLUDING RECTUM FOR THE YEARS 1947–1948 AT THE BINGHAMTON CITY HOSPITAL

FRANK D CONOLE, M D , and RICHARD J PHALEN, M D , Binghamton, New York

(From the Binghamton City Hospital)

DURING the fiscal year starting in June, 1947, and ending June, 1948, the surgical service of the Binghamton City Hospital encountered 35 malignant lesions of the large bowel (Table 1) Because of the fact that so many worth-while advances have resulted from a better understanding of the basic physiology and pathology, coupled with chemotherapy and antibiotic therapy, technical advancement, as applied to a broadening of the surgical management of these lesions, has occurred The surgeon of today is better able to deal so efficiently with these lesions of the large bowel, not because he is always a better technician but because, step by step, a number of the difficult problems involved in colon surgery have been solved So much is this true that it has been stated, and perhaps rightly so, that the real problem left unsolved is that of early diagnosis We should concern ourselves more with this problem than with trying to perfect some new type of surgical operation to eradicate colonic neoplasms

Dehydration in its various forms, so common in these patients, can best be corrected by establishing adequate fluid intake and checking carefully the urinary output Blood chemistry, nitrogen, electrolyte balance, and serum protein levels are frequently disturbed to some degree Anemia and avitaminosis must not be overlooked A correlation of all these factors and the institution of necessary corrective measures are enacted during the preoperative period The use of chemotherapy before colon surgery is a moot question If it is carefully administered, the likelihood of its being harmful is far less than the beneficial results it offers

It must be stressed that the surgeon himself should have a good working knowledge of these recent physiologic and chemotherapeutic advancements He cannot relegate such detail in its entirety to anyone The over-all supervision is his responsibility There are many types of surgical procedures to be used in dealing with colonic malignancy, as this series of cases will show Fortunately, the operative mortality has been low, this speaks well for the surgical group The fallacies are to be found in the fact that no accurate follow-up data have been acquired

The right colon, because of the semiliquid content within and the involvement of the vascular and lymphatic bed, lends itself best to a right colectomy with ileotransverse colostomy Among the eight patients presenting a lesion in this section of the bowel five had this type of resection, all done by different surgeons, with no operative mortality The remaining three cases were treated in a different manner In one an ileotransverse colostomy without resection of the

TABLE 1.—MALIGNANT LESIONS OF THE LARGE BOWEL IN 35 PATIENTS

choline acetylase itself If the latter should be found to be true, a convenient screening method for the detection of drugs with potential activity in paralysis agitans would be available

The evaluation of remedies in paralysis agitans is difficult not only because of the suggestibility of the patients, the day to day variations in their condition, and the incidence of spontaneous remissions, but particularly because all the remedies at our disposal are at present only palliative The changes which are observed, even if real and reproducible, cannot be accurately measured or recorded at present so that evaluation of a drug depends on the subjective estimate of the patient and the clinical impression of the observer This study showed that Thephorin may prove effective in about one half of the cases It was equally effective in postencephalitic as in idiopathic cases *It differed in this respect from scopolamine* and other solanaceous alkaloids which were effective, at least for a time, in almost all cases of postencephalitic parkinsonism but were, as a rule, ineffective in cases of other origin Although Thephorin was of value when given as the only treatment, it has been found that certain cases deriving great benefit from scopolamine may improve still further if additional doses of Thephorin are given Many postencephalitic patients obtain great relief of symptoms from scopolamine for many years Gradually, the effect of the drug diminishes until in the end it is no longer useful Thephorin has been found of value in three such cases

Two other drugs which are sometimes effective in paralysis agitans of postencephalitic or other origin are Benadryl and myanesin Benadryl appears to be of some value in about three fourths of patients, while myanesin shows desirable effects in about one third of the cases Benadryl appears to work particularly well in very old patients suffering from the so-called arteriosclerotic form of paralysis agitans The type of patient likely to benefit from myanesin can be recognized only by actual trial of the drug All of our patients who benefited from Thephorin had received Benadryl and myanesin on previous occasions Although many of them benefited from one or both of the drugs, the improvement after Thephorin was much greater than that felt or observed after Benadryl or myanesin On the other hand, there were patients who did not tolerate or did not benefit from Thephorin who were very favorably influenced by myanesin or Benadryl

The most frequently encountered side action of Thephorin was insomnia The incidence of side-effects of Thephorin in patients suffering from paralysis agitans is rather interesting Thephorin given to healthy people or to patients suffering from various allergic disorders caused side-effects in a smaller proportion of cases [14 15] It appears that the pathologic mechanisms which are responsible for paralysis agitans are particularly sensitive to the effect of Thephorin and suggests that the drug has a direct influence on these mechanisms

Summary

Thephorin is a useful drug in the symptomatic treatment of certain cases of paralysis agitans The drug appeared equally effective in cases of postencephalitic and idiopathic origin Tremor, rigidity, fine movements, facial expression, speech, gait, and pain were favorably influenced Thephorin was administered *alone or in conjunction with alkaloidal or other* drugs which the patients had been taking before treatment with Thephorin had been commenced The improvement was maintained as long as the drug was administered and disappeared on discontinuation of Thephorin Although Thephorin was effective in only about one half of the cases in which it was tried, the improvement obtained in certain cases justifies the trial of the drug in all cases which are not satisfactorily controlled by other remedies

---

My thanks are due to Dr W S McCann Dr P Garvey and Dr E Green for permission to use the drug on their patients

HESPERIDIN-C AND CAPILLARY FRAGILITY

WINIFRED C LOUGHLIN, M D , New York City

(From the Diabetes Clinic, New York Post-Graduate Medical School and Hospital)

WHETHER hesperidin is actually vitamin P has been discussed in innumerable papers [1–3] Suffice it to say here that vitamin P was so named by Szent-Györgyi and his collaborators in 1936 when they found that extracts of paprika and of lemon juice benefited hemorrhagic cases which had failed to respond to pure ascorbic acid The name indicated some curative substance in these extracts which had a vitamin-like action on the permeability of capillaries [4] This curative substance was later found to be a crystalline flavone and was named "citrin" and later still was believed to be a mixture of crystalline substances called eriodictin, now thought to be hesperidin (a flavonone glucoside), eriodictyol glucoside, rutin (a quercitrin-like glucosone), chalcone compounds (hesperidin chalcone and methyl chalcone), and many flavone derivatives [5–7] It is not the purpose of this paper to discuss the various comparative values of any of these substances, singly or in combinations, to fulfill the functions of vitamin P Rather, its purpose is to present a clinical study on the effect of hesperidin and ascorbic acid in some cases of diabetes mellitus and of hypertension

Materials and Methods

The medication used in this study was in the form of a compressed tablet containing 50 mg of hesperidin and 50 mg of ascorbic acid * Because vitamin P is associated with vitamin C in nature it was desirable to combine the two and enhance a theoretic synergistic action The dosage varied from three to twelve tablets daily

The only other materials used were those necessary for carrying out the testing to display the Rumpel-Leede phenomenon The sphygmomanometer cuff was inflated where applied above the elbow, and the pressure was held at a level midway between the systolic and diastolic readings for six minutes Six minutes became the standardized time in this study, because the first patient selected for study could tolerate the continued positive pressure no longer His entire lower arm became literally so peppered with thousands of petechiae that a numerical reading would have been impossible, a similar massive petechialization was found in many more patients The cuff was then deflated, and after five minutes a count of the petechiae was made in two circles (2 5 cm each) located 4 cm below the antecubital fold An average of 20 or more petechiae was considered to be evidence of abnormal capillary fragility

* Supplied by the National Drug Co of Philadelphia.

Clinical Data

Twenty-five patients were selected for study because all had evidence of abnormal capillary fragility Twenty had diabetes mellitus Ten of these had various complications of the disease four had peripheral neuropathy, two had hepatomegaly, one had a cataract and recurrent cheilosis, two had Kimmelstiel-Wilson syndrome, five had retinopathy (grades 3 and 4), two had hypercholesterolemia, and seven had hypertension without albuminuria or retinopathy All the diabetics were moderately well controlled, and their diets and insulin dosages were not radically altered during the course of study All but two were taking insulin Five patients had hypertensive disease All of these were free of its complications except one who had chronic azotemia About one half of the 25 cases were private patients, and the others were outpatients in the clinic There were 18 women and seven men, their average age was fifty-three years (ranging from twenty-two to sixty-seven) The average duration of diabetes mellitus was eight years (ranging from six months to twenty-five years) and that of the hypertension was four years (ranging from one to fifteen years)

Restudy of the Rumpel-Leede phenomenon in the manner described was carried out once monthly and restudy of the eyegrounds was done at the same time The average length of time the drug was taken and the patients studied was eight months (ranging from two months in those with the least abnormal capillary fragility to eighteen months in those with the most) Before administration of the drug was started, ten patients' plasma was studied for levels of vitamin C All were found to have levels above that of adequacy (ranging from 0 82 to 1 90 mg in 100 cc plasma) These ten and the remaining 15 had no signs of scurvy

Observations

Cases with diabetes mellitus and those with hypertension alone will be discussed separately It will be found easiest to discuss both groups as to extent of pretreatment capillary fragility Those with diabetes will be taken up first

Cases with 4-Plus Capillary Fragility—These had 75 or more petechiae before treatment, all had the massive petechialization previously

cecum was considered the procedure of choice because of liver metastasis A Mikulicz resection was done with a death on the tenth postoperative day One patient, apparently not obstructed, was explored, a biopsy was taken, and because of extensive intra-abdominal metastases nothing more was considered necessary

The location of the lesion, the free mobility of the transverse colon (except for the splenic flexure), and good blood supply allow for the choice of several different procedures It is interesting to note that the average age is a bit higher than in the previous group, and also the condition is more prone to occur in women The Mikulicz procedure as carried out in two of the six patients resulted in an operative fatality in each case In one a portion of the jejunum was resected at the same time An ileotransverse colostomy in a patient with generalized intra-abdominal metastases resulted in death on the seventy-fifth day, the picture being complicated by rather severe Parkinsonism and diabetes A patient who underwent resection of the right colon with ileotransverse colostomy, applicable only in lesions in the right third of the colon, had a reasonably short hospital stay and a very good operative result A resection with primary anastomosis gave a very good operative result and the shortest hospital stay (twenty-three days) The Mikulicz resections referred to above were not put to an entirely fair test In the second case the lesion was located in the splenic flexure, perhaps the most difficult spot in the entire colon from the standpoint of technical difficulties encountered It is possible a cecostomy or Wangensteen colostomy at a point proximal to the resection might have been helpful

The sigmoid colon or, as the English anatomist prefers to call it, the pelvic colon is almost always quite mobile It does not include that portion of bowel below the peritoneal reflection which for the sake of eliminating confusion can best be called the rectum, the term "rectosigmoid" being eliminated Resection with primary anastomosis was preferred to the exteriorization procedures, and only one colostomy was done Of the ten lesions encountered, a resection with primary anastomosis done in five cases resulted in only one operative death A supracervical hysterectomy and bilateral salpingo-oöphorectomy were successfully accomplished in one of the cases The one fatality was due to sepsis, which results from leakage at the suture line far more commonly than spillage at the time of operation Exteriorization (Mikulicz) done in three cases did result in a shorter initial hospital stay, but, when one considers that the incidence of spontaneous closure without actual surgery is less than 15 per cent, further hospitalization is more likely One patient was treated by anterior resection (Hartman), the choice of this procedure should be limited to the poor risk, elderly patient A divided colostomy was done because of pelvic abscess The possibility of an associated diverticulitis with perforation as a causative factor must be considered In only one patient was a preliminary cecostomy resorted to as a decompressive measure The fact that the patient came to a successful resection with anastomosis speaks well for a procedure (cecostomy) that is not too useful most of the time

It was in the rectum that most of the lesions (11) were encountered, the greater number (9) being found in males The age incidence was a bit higher than in the descending colon and sigmoid group There must be something missing because it is difficult to believe that no operative death was revealed The one-stage abdominoperineal resection done in five cases, with no deaths and an average stay in the hospital of thirty-five days, is evidence of very excellent surgery, it even speaks well for the procedure The more complicated "pull through" Babcock abdominoperineal resection in two cases had no operative mortality A morbidity did occur, and an eventual hospitalization months later and death calls for an explanation in itself Loop colostomy without biopsy confirmation (two cases), in the opinion of the author, borders on a laissez-faire attitude A divided colostomy done in one case with extensive pelvic, abdominal, and liver metastases should be reserved solely for this type of case

In most instances the surgical procedures resorted to are in line with the accepted thought by those who are doing a greater volume of work in the larger clinics The operative results, very good as they are, may be misleading because of an inadequate follow-up, which may very well be done at a later date

EXPERIENCE WITH THE BARTON FORCEPS IN A SMALL URBAN HOSPITAL

LYMAN G BARTON, JR, M D, F A C S, Plattsburg, New York

(From the Champlain Valley Hospital)

SINCE all previous reports on the use of the Barton forceps have emanated from large teaching institutions, a comparative study from the small urban community which might almost be termed the birthplace of the Barton forceps may be of some value One criticism of the Barton forceps has been that, while it might have a limited use in the hands of skilled obstetricians, it was no instrument for the general practitioner The results obtained in this small institution, Champlain Valley Hospital, would tend to disprove that statement, since all deliveries here were performed by men who are in no sense specialists but have become familiar with the use of the forceps either from instruction by the inventor or, in an occasional instance, by the writer Any apparent undue enthusiasm for the forceps exhibited by the writer can be perhaps pardonably excused on the basis of filial onde

Since, to date, any statistical study tends to upport the superiority of the forceps in properly elected cases, it seems unfortunate that either om ultraconservatism or lack of familiarity ith the instrument some obstetricians continue use what should be obsolete methods of deliv- y The late Dr DeLee in commenting on rceps deliveries once claimed that he could ef- ct any delivery with classic forceps as well as th any modifications By analogy one can remove an inaccessible nut with a hammer and cold chisel but how much harder it is on the nut

The one feature most stressed by the late Dr Barton was the damage done to the fetal head, particularly tentorial tears, resulting from the tangential force exerted by improper cephalic applications This force, plus the force exerted by traction in an improper axis by the classic forceps, even with axis traction, is undoubtedly responsible for varying degrees of intracranial damage Beyond dispute the ideal forceps delivery is one obtained by perfect cephalic application followed by traction in the pelvic curve allowing rotation to occur where it should in that particular pelvis In the writer's experience midpelvic arrest occurs in a very high percentage where this ideal delivery cannot be performed with the classic forceps

According to Caldwell, Molov, and D'Esopo, gynecoid and android types of pelves transverse positions occur in approximately 70 per cent of the cases, and it is only in the anthropoid types of pelves with the long oval inlet that the oblique anterior and posterior positions occur [1] Since the Barton forceps was designed particularly for transverse arrests and is the only instrument that permits an exact cephalic and pelvic application at the same time, it should follow that the Barton forceps are indicated in approximately 70 per cent of all midpelvic arrests While it is very easy to obtain an exact cephalic application on an unengaged or floating head with the Barton forceps and also to obtain traction in the axis of the superior straight, this procedure is no longer considered good practice and should not be attempted

While the Barton forceps was designed primarily for use in arrests in the transverse or posterior occiput positions, the writer has on more than one occasion failed to obtain a satisfactory cephalic application in the so-called anterior position with the classic forceps but has obtained a good cephalic application with the Barton forceps The expression "so-called anterior position" is used since the occiput is really just as near the transverse position as it is the anterior position Consequently, in attempting a biparetal application with the classic forceps the instrument has to be rotated, losing the pelvic curve in exact proportion to the degree in which it is rotated and becoming, to all intents and purpose, a straight forceps Actual complete rotation of the occiput to the arch is the last thing to occur in the large majority of cases, and it is only after this has occurred that the ideal combination of a perfect cephalic and pelvic application can be obtained with the classic forceps This may sound radical but nevertheless has been our experience

Technic

The actual method of application and use of the Barton forceps has been adequately described elsewhere [2] However, there are a few minor points which might be worth mentioning even if they may seem truisms Many of these obviously apply to all forceps deliveries First it should be determined that forceps delivery is indicated—briefly that labor has been arrested after a fair trial—secondly, that this arrest is due not to absolute disproportion or restraining soft parts but rather to either faulty position or

mentioned There were seven cases in this group They included those with retinopathy, and all had one or more of the complications mentioned above, including both cases of Kimmelstiel-Wilson syndrome They were those with the longest duration of their illness—an average of ten years They were treated continuously for an average of eleven months, and all received 12 tablets daily The petechiae counts varied downward and upward during the course of treatment, but the trend was downward However, the count never reached normal, and increases in dosage resulted in no further improvement The final average count was 40 The retinopathy was not improved in a single case At the end of the course of treatment all still had massive petechialization of the forearm from the cuff, but to a lesser degree

Cases with 3-Plus Capillary Fragility—These had from 50 to 74 petechiae before treatment There were six cases in this group Only one had any complication, a cataract and recurrent cheilosis They had had their illnesses for an average of five years (except for one case who had had it for twenty-five years) These were treated for an average time of five months and received 9 tablets daily During this time there was a steady downward trend in the capillary fragility, and it reached an average level of 36 Higher dosage resulted in no further improvement

Cases with 2-Plus Capillary Fragility—These had from 20 to 49 petechiae before treatment There were seven cases in this group, of which two had complications (both hypercholesterolemia) The average duration of their diabetes was six years They were treated for an average of six months, and most of them took 3 tablets daily, a few 6 tablets There was a steady downward trend of the petechiae count to normal, reaching an average of 12 All cases showed as few as three or four petechiae at one or more times

Of the five patients with hypertensive disease, two fell into the 4-plus capillary fragility group and three into the 3-plus The initial petechiae count was an average of 55 They received the medication for an average time of eight months, and most responded to a dosage of 3 tablets daily All attained normal petechiae counts at one or more times, including the patient with azotemia, and the final average count was 11 All showed a wide fluctuation in the petechiae throughout treatment

Summary

Twenty patients with diabetes mellitus and five with hypertensive disease were studied for abnormal capillary fragility Ten of the diabetics had complications, including five with retinopathy One hypertensive had azotemia

The extent of the capillary fragility was graded as to severity All were assumed to be free of scurvy before treatment because of either adequate plasma vitamin C levels or absence of clinical signs

All were treated for an average of eight months with hesperidin-C, a preparation thought to have vitamin P activity

Of the diabetics, those with the most abnormal capillary fragility were on the whole those with complications, with retinopathy, and with the longest duration of the disease With high dosage for a long period these patients showed a diminution in the capillary fragility from a 4-plus extent to a 2-plus extent. Cases with a pretreatment capillary fragility of a 3-plus degree showed improvement to the same level Patients with mildly abnormal capillary fragility (2-plus) responded to small doses and showed a return to normal No improvement in retinopathy occurred

Of the hypertensives, all showed a good response to treatment after eight months, regardless of the severity of the initial capillary fragility

There were no toxic reactions to the hesperidin-C

Conclusions

1 Severity of abnormal capillary fragility in diabetes mellitus is directly related to the duration of the disease and to the presence of complications and of retinopathy

2 Markedly abnormal capillary fragility in diabetics responds to a high dose of hesperidin-C over a long period of time but does not reach a normal state Nor does moderately abnormal capillary fragility

3 Mildly abnormal capillary fragility in diabetics responds to hesperidin-C and becomes normal

4 Diabetic retinopathy is not improved by hesperidin-C

5 Abnormal capillary fragility in hypertension becomes normal with hesperidin-C therapy During the course of treatment there is a wide fluctuation in the extent of the capillary fragility

6 Hesperidin-C causes no toxic reactions

EXPERIENCE WITH THE BARTON FORCEPS IN A SMALL URBAN HOSPITAL

LYMAN G BARTON, JR , M D , F A C S , Plattsburg, New York

(*From the Champlain Valley Hospital*)

SINCE all previous reports on the use of the Barton forceps have emanated from large teaching institutions, a comparative study from the small urban community which might almost be termed the birthplace of the Barton forceps may be of some value One criticism of the Barton forceps has been that, while it might have a limited use in the hands of skilled obstetricians, it was no instrument for the general practitioner The results obtained in this small institution, Champlain Valley Hospital, would tend to disprove that statement, since all deliveries here were performed by men who are in no sense specialists but have become familiar with the use of the forceps either from instruction by the inventor or, in an occasional instance, by the writer Any apparent undue enthusiasm for the forceps exhibited by the writer can be perhaps pardonably excused on the basis of filial pride

Since, to date, any statistical study tends to support the superiority of the forceps in properly selected cases, it seems unfortunate that either from ultraconservatism or lack of familiarity with the instrument some obstetricians continue to use what should be obsolete methods of delivery The late Dr DeLee in commenting on forceps deliveries once claimed that he could effect any delivery with classic forceps as well as with any modifications By analogy one can remove an inaccessible nut with a hammer and cold chisel but how much harder it is on the nut

The one feature most stressed by the late Dr Barton was the damage done to the fetal head, particularly tentorial tears resulting from the tangential force exerted by improper cephalic applications This force, plus the force exerted by traction in an improper axis by the classic forceps, even with axis traction, is undoubtedly responsible for varying degrees of intracranial damage Beyond dispute the ideal forceps delivery is one obtained by perfect cephalic application followed by traction in the pelvic curve allowing rotation to occur where it should in that particular pelvis In the writer's experience midpelvic arrest occurs in a very high percentage where this ideal delivery cannot be performed with the classic forceps

According to Caldwell, Moloy and D'Esopo, in gynecoid and android types of pelves transverse positions occur in approximately 70 per cent of the cases, and it is only in the anthropoid types of pelves with the long oval inlet that the oblique anterior and posterior positions occur [1] Since the Barton forceps was designed particularly for transverse arrests and is the only instrument that permits an exact cephalic and pelvic application at the same time, it should follow that the Barton forceps are indicated in approximately 70 per cent of all midpelvic arrests While it is very easy to obtain an exact cephalic application on an unengaged or floating head with the Barton forceps and also to obtain traction in the axis of the superior straight, this procedure is no longer considered good practice and should not be attempted

While the Barton forceps was designed primarily for use in arrests in the transverse or posterior occiput positions, the writer has on more than one occasion failed to obtain a satisfactory cephalic application in the so-called anterior position with the classic forceps but has obtained a good cephalic application with the Barton forceps The expression "so-called anterior position" is used since the occiput is really just as near the transverse position as it is the anterior position Consequently, in attempting a biparetal application with the classic forceps the instrument has to be rotated, losing the pelvic curve in exact proportion to the degree in which it is rotated and becoming, to all intents and purpose, a straight forceps Actual complete rotation of the occiput to the arch is the last thing to occur in the large majority of cases, and it is only after this has occurred that the ideal combination of a perfect cephalic and pelvic application can be obtained with the classic forceps This may sound radical but nevertheless has been our experience

Technic

The actual method of application and use of the Barton forceps has been adequately described elsewhere [2] However, there are a few minor points which might be worth mentioning even if they may seem truisms Many of these obviously apply to all forceps deliveries First it should be determined that forceps delivery is indicated—briefly that labor has been arrested after a fair trial—secondly that this arrest is due not to absolute disproportion or restraining soft parts but rather to either faulty position or

lack of "vis-a-tergo" An exact diagnosis of position of the presenting part must then be made, *feeling an ear if necessary* One must be as certain as possible that one is not dealing with a pelvis in which the outlet is smaller than the inlet (This is one instance in which irretrievable trouble may develop) The cervix should be completely dilated and preferably retracted over the head Traction should be moderate and applied only during uterine contractions If descent and rotation do not occur, attempts at delivery by this method should be abandoned before damage has been done

The above naturally applies to all forceps deliveries In using the Barton forceps particularly, ambidexterity is useful Right-handed individuals should be trained from the start in making all vaginal and rectal examinations with the left hand, whereas the reverse would be true in the left-handed person *The anterior blade* of the Barton forceps is always introduced first, and this maneuver alone is often sufficient to convert a posterior occiput to a transverse occiput as well as to overcome an anterior asynclytism by bringing the sagittal suture exactly in the midline of the superior straight It is immaterial whether the anterior blade is swept over the occiput or the synciput If the anterior blade is to be swept around the right side of the pelvis, for instance over the occiput of a right occiput transverse, it is more convenient to use the left hand as the vaginal hand, whereas the right hand is used in sweeping the blade around the left side of the pelvis In introducing the posterior blade the tip of the blade should be kept close to the posterior side of the fetal head, and at times it is necessary to point it slightly lateral to the promontory, later moving the blade back into the midline after it has been introduced This maneuver makes it a bit easier to place the blade exactly between the fetal head and the sacrum During the introduction of either the anterior or posterior blade it may be necessary to dislodge the fetal head very slightly upward so that the blades will slip into place easily The maneuver suggested by Studdiford for obtaining flexion of the head is very useful, and if good flexion is not already present, it should be used before traction is exerted[3] The posterior fontanelle should always be palpable exactly between the two blades and close to their junction

As to the question of direct traction versus "axis traction," the experienced operator who knows exactly in which direction traction should be applied and also just when rotation should occur can dispense with the axis traction bar The average operator, however, should be more successful using the axis traction bar which is so constructed that it becomes, in effect, a universal joint and permits the head to rotate whenever it should The writer uses what might be termed a compromise between the two methods, exerting traction on the bar with one hand and steadying the handles with the other In this manner one is not so apt to exert too much force

While the forceps were never designed for what might be termed "artificial rotation" of the head, viz , rotation to an anterior position above the outlet, nevertheless, if and when this is thought to be indicated, rotation with the forceps is much easier than manual rotation followed by application of classic forceps, which is, in our experience, never ideal at that level

Results

As previously stated, this report is based on experience in a small urban community, all deliveries were performed by members either of the active or courtesy staff The cases represent private patients as well as cases sent in from a fairly wide radius because of complications Over the ten-year period 1936 through 1945 there was a total of 3,707 deliveries Of these 509, or 13 7 per cent, were delivered by operative measures The frequency of various types of operative deliveries is shown in Table 1

TABLE 1 —FREQUENCY OF TYPES OF OPERATIVE DELIVERIES IN 509 CASES

Deliveries	Number of Cases	Per Cent
Cesarean section	50	1 3
Breech extraction	14	0 38
Version and extraction	9	0 24
Craniotomy		
High forceps	10	0 26
Midforceps	134	3 6
Low forceps	282	7 6

The rather high incidence of high forceps deliveries is to be regretted, these deliveries occurred in the earlier years of this report, and half of them were done by one man with no record of the type of forceps used Three stillbirths resulted, two from intracranial damage and one from asphyxia from a prolapsed cord There was one maternal death in this group due to postoperative pneumonia

The relatively low incidence of cesarean sections, versions, and breech extractions should be ample proof that no effort was made to avoid the responsibility or lower the frequency of midforceps deliveries I believe that the indication for midforceps deliveries in this clinic approximated those in the average clinic, i e , midpelvic arrest after a fair test of labor, usually about a two-hour second stage There were 110 mid-

forceps deliveries in which the Barton forceps were used, while the classic forceps were used in 24 cases This represents quite closely the relative frequency in which the head descends into the midpelvis in a transverse position as stated by Caldwell *et al*, classical forceps being used for the smaller number of anterior positions No distinction is being made in this report relative to just what type of forceps was used once rotation was complete and the head was on the perineum Also, transverse and posterior occiput midpelvic arrests have not been subdivided, since posterior occiput positions almost automatically become transverse positions during application of the Barton forceps

In the 110 midforceps deliveries with Barton forceps there were two neonatal deaths, one due to impacted shoulders and one due to asphyxia This represents a fetal mortality of 1 8 per cent In the 34 midforceps deliveries with classic forceps there were likewise two stillbirths representing 5 8 per cent mortality In one of these there had been failure at forceps delivery in the home but easy delivery in the hospital, the time of fetal death was not stated

The fetal mortality for the group as a whole was 2 7 per cent, an incidence which certainly compares favorably with the report from one institution where the Barton forceps is relegated to the museum and a fetal mortality rate of 22 8 per cent in midforceps deliveries is admitted There was one maternal death following midforceps deliveries with the Barton forceps [4] This occurred on the fourteenth postpartum day from pulmonary embolism as the patient was dressing preparatory to going home The 282 low forceps deliveries resulted in seven fetal deaths, an incidence of 2 4 per cent Thus, the total of all forceps deliveries was 426 with a total of 11 stillbirths or neonatal deaths, a gross fetal mortality of 2 5 per cent The Kielland forceps has never been used in this institution

Since this report is submitted in an effort to substantiate our belief in the superiority of the Barton forceps in properly selected cases, no analysis has been included here of our results in versions and breech extractions with, at times, forceps to the aftercoming head Suffice it to say that our results there are nothing of which to be proud there being a 17 per cent incidence of fetal deaths from intracranial damage in this type of delivery

Conclusion

In conclusion, we admit that this series is too small to constitute a basis for any very definite observations However, we submit this report in the hope that it may encourage the wider use of the Barton forceps in the class of cases for which it was originally designed No forceps, regardless of how cleverly it is conceived, will overcome absolute disproportion, and it is only by careful cephalic application and, above all, avoidance of undue and faulty traction that one can hope to lower the incidence of intracranial damage

TREAT LEUKEMIA WITH RADIOACTIVE PHOSPHORUS

Encouraging results in treating one form of leukemia, or cancer of the blood-forming tissues, with radioactive phosphorus, are reported on the basis of studies made at the Radiation Laboratory and Divisions of Medical Physics and Radiology, University of California, Berkeley and San Francisco

Writing in the issue of June 18 of the *Journal of the American Medical Association*, Drs John H Lawrence, Berkeley, B V A. Low-Beer, San Francisco and James W J Carpender, Chicago, say that out of 100 patients treated for chronic lymphatic leukemia with radioactive phosphorus and x-rays, one third were alive five years after the onset of the disease "When compared with five-year end results in other types of cancer, these results are relatively good"

This type of leukemia is one of the major forms of the disease, although not the most common. It may develop over a period as long as two years, in contrast to the terrible rapidity with which acute leukemia progresses

A CLINICAL EVALUATION OF ETHINYL ESTRADIOL IN THE MENOPAUSE

HILLIARD DUBROW, M D , CHARLES S POOLE, M D , and ROBERT I WALTER, M D , New York City

(*From the Gynecological Clinic, Mount Sinai Hospital*)

ETHINYL estradiol was produced by Inhoffen and Hohlweg in 1938 by the introduction of an ethinyl group into the seventeen carbon atoms of alpha estradiol [1] This synthesis markedly increased the oral activity of alpha estradiol, and it has been estimated that estinyl estradiol is 15 to 50 times more potent than alpha estradiol orally, and 4½ to 20 times more potent than diethylstilbesterol

In 1941, one of us (R I W) was coauthor of one of the early clinical reports on the use of ethinyl estradiol in the menopause [2] It was shown that ethyl estradiol is (1) highly potent orally, (2) capable of relieving menopausal symptoms in a high percentage of patients in four to seven days on an average daily dosage of 0 45 mg , and (3) capable of inducing full estrogenic effects in the genital tract as judged by vaginal smear and biopsy studies However, because of the high incidence of toxic symptoms, chiefly gastrointestinal, ethinyl estradiol was not recommended for general clinical use Subsequent reports have indicated that toxic symptoms can be reduced by reduction in dosage without loss of beneficial effect [3–5]

At this time, we wish to report our results with ethinyl estradiol in the treatment of a series of 34 menopausal patients Nineteen were in the natural menopause, 13 were surgical castrates, and two were x-ray castrates

Dosage

The initial dosage in all patients was 0 05 mg daily For the majority of patients this was also the optimum maintenance dosage (Table 1)

TABLE 1 —DOSAGE NECESSARY FOR OPTIMUM RESULTS

Dosage Necessary for Optimum Results (Mg. per Day)	Number of Patients	Percentage
0 02	2	6
0 05	22	65
0 10	9	26
0 15	1	3

Ethinyl estradiol (trade name Estinyl) was generously supplied by the Schering Corporation Bloomfield New Jersey

Side-effects

Three patients noted vaginal spotting while on maintenance dosage The bleeding was minimal and stopped with the discontinuance of therapy In no instance was it necessary to withhold therapy because of gastrointestinal symptoms. This is in sharp contrast to the high incidence of toxic symptoms previously reported from this clinic [2] It is clear, as has been noted by others, that ethinyl estradiol in high doses will cause gastrointestinal irritation which is almost completely eliminated by reducing in dosage Fortunately, a maintenance dosage of 0 05 mg gives good therapeutic results and is associated with low toxicity

Results

Satisfactory results were obtained in 33 of the 34 patients treated (Table 2)

TABLE 2 —RELIEF OF SYMPTOMS

Relief of Symptoms	Number of Patients	Percentage
Complete	29	85
Moderate	4	12
Failure	1	3

Summary

1 In a series of 34 menopausal patients, treated with ethinyl estradiol, there was complete relief of symptoms in 29, moderate relief in four, and one failure

2 The average maintenance dosage was determined as 0 05 mg daily

3 No toxic symptoms occurred in a maintenance dosage of 0 05 mg daily

4 Ethinyl estradiol is a potent, orally active estrogen, combining a high therapeutic efficiency with a low incidence of toxic symptoms

THE USE OF AN INTERMITTENT AMBULATORY SCHEDULE OF PENICILLIN IN OIL AND WAX IN THE TREATMENT OF EARLY LATENT SYPHILIS AND SYPHILIS IN PREGNANCY

GEORGE E PEABODY, M D , and BRUCE WEBSTER, M D , New York City

(From the Department of Medicine of the New York Hospital and Cornell University Medical College)

PENICILLIN in oil and wax probably will not feature in the treatment of syphilis in the future due to the more recent development of improved action-delaying vehicles Results from its use to date, however, indicate the therapeutic efficacy of the intermittent administration of penicillin to ambulant patients with various forms of syphilis and thus warrant evaluation of its current status

During the past two years, penicillin in oil and wax has been used in the syphilis clinic of the New York Hospital in the treatment of early latent syphilis and syphilis in pregnancy on an intermittent ambulatory schedule During this period, 61 cases of early latent syphilis and 57 cases of syphilis in pregnancy have been treated on a schedule of 600,000 units of intramuscular penicillin in oil and wax twice a week for six weeks, with concurrent intramuscular bismuth subsalicylate 0 2 Gm weekly for twelve weeks (Four of the 57 maternal syphilis group had received no prior therapy for early latent syphilis and are included in the early latent syphilis total as well)

Early in 1946, at the time this schedule was devised, no information was available as to the efficacy of penicillin in latent syphilis The bismuth therapy was added in an effort to prolong the time period over which treatment was carried out In July, 1948, this agent was omitted from the treatment schedule, and subsequent observation has indicated that the efficacy of the treatment regime was not influenced thereby

Success of treatment has been evaluated on the basis of rapidity of persistent seroreversal and lack of subsequent infectious or serorelapse in cases of early latent syphilis and the delivery of syphilis-free infants in cases of maternal syphilis However, it must be realized that syphilis in pregnancy is not an ideal form for the evaluation of therapy, since most of these patients, if previously treated, will give birth to normal infants

Results

Of the 61 early latent syphilis patients treated, 53 (87 per cent) have shown partial or complete seroreversal, 38 (62 per cent) have become totally seronegative, while 8 (13 per cent) remain seropositive The average time of beginning seroreversal was three months, with complete seroreversal achieved in about five and one-third months Timing the follow-up from the beginning of treatment, there were 30 cases which were followed between twelve and twenty months, 18 from six to twelve months, and 13 cases less than six months Twenty-two cases of the year-or-more follow-up group (73 per cent) have attained complete seroreversal, and four more have shown a decrease in titer The average time of beginning seroreversal in this group was three and one-half months, with complete seroreversal in a total of six and one-half months Of the 18 cases in the six-to-twelve months group 13 (72 per cent) became seronegative, and the remaining five have shown a definite decline in titer The average time of beginning seroreversal in this group was two and one-half months, with complete seroreversal in four months Of the 13 cases followed less than six months since the beginning of treatment, three have so far become seronegative, and six more now show a decreased titer The three cases becoming seronegative did so in an average of two months None of these cases has had a subsequent relapse, either infectious or serologic, following treatment

The 57 cases of maternal syphilis treated with penicillin in oil and wax during their pregnancies include six with previously treated secondary syphilis, four untreated and six treated early latent syphilis, four untreated and 27 treated late latent syphilis, two untreated asymptomatic neurosyphilis, one treated tabes dorsalis, and one untreated and six treated latent congenital syphilis Of the 11 cases not treated before four were patients with early latent syphilis who became seronegative, while one with late latent syphilis showed partial seroreversal Ten of the total of 57 became seronegative, including four cases of untreated early latent syphilis, two cases of secondary syphilis recently treated and with partial seroreversal already, three cases of treated late latent syphilis, and one of latent congenital syphilis previously treated Three cases of late latent syphilis, two previously treated, showed incomplete seroreversal Twenty-five of the 57 cases had been treated

Aided by grants from the Syphilis Study Section of the National Institute of Health and the Barbara Henry Research Fund

before and were seronegative throughout, being re-treated during their pregnancy as a precautionary measure In none of these cases were treatment reactions, such as local discomfort at the site of injection or hypersensitivity reaction, significant enough to necessitate cessation of therapy No syphilitic infants were delivered in any case

In addition to its use in the treatment of early latent syphilis and syphilis in pregnancy, penicillin in oil and wax on the same treatment schedule was used for other types of syphilis in the syphilis clinic of the New York Hospital, either because of the convenience of ambulatory treatment in certain cases of infectious syphilis, neurosyphilis, or late latent syphilis, or as alternative therapy because of arsenical reactions in cases of late latent syphilis

Of 17 cases of early infectious syphilis so treated, two cases were of seronegative primary syphilis, six seropositive primary syphilis, and nine secondary syphilis Fourteen of the 17 are now seronegative The three cases of seronegative syphilis achieved a rapid, complete, and sustained clinical response Five cases with seropositive primary syphilis began seroreversal in an average of one and one-half months, becoming seronegative in an average of three months Six secondary syphilis patients began seroreversal in an average of two and one-third months and achieved complete seroreversal in four months This represents for 11 early infectious cases an average beginning seroreversal in two months with complete seroreversal in three and one-half months Of the remaining three of the 17 cases, one is still under treatment, one has lapsed from follow-up, and one remains seropositive after six months

Of the seven cases of neurosyphilis treated under this regime, all have shown improvement in the cerebrospinal fluid, and the symptomatic cases have experienced relief of symptoms The results of this scheme of treatment are comparable to those obtained by the administration of four to six million units of crystalline penicillin-G over a two-week period

Twenty-two of the cases of previously untreated late latent syphilis and three cases of late benign syphilis were treated with penicillin in oil and wax The results in these cases, in terms of reduction in titer or clinical response were comparable with those obtained by intensive penicillin regimes (4,200,000 units crystalline penicillin-G over two weeks)

Discussion

The significance of our results must be considered in terms of the limited number of cases treated On the basis of the observations listed above, it would appear that penicillin in oil and wax, given in doses of 600,000 units twice a week for six weeks with concurrent bismuth subsalicylate in oil in 0 2-Gm doses, one a week for twelve weeks, is an effective agent in the treatment of early latent syphilis and compares favorably with the other commonly used treatment schemes The Cooperative Clinical Group reported that of 514 arsenic-treated early latent syphilis patients, one half of them showed satisfactory seroreversal and one third exhibited unsatisfactory results [1] A recent report of 134 cases of early latent syphilis treated triweekly with arsenicals revealed that during a three-year period of follow-up 33 became seronegative, and 41 more showed a reduction of titer [2] Therefore, the 72 per cent seroreversal obtained in 48 cases of early latent syphilis treated with penicillin in oil and wax in the present study and followed for over six months is considerably better than the results given by arsenotherapy Further, this treatment regime has the advantage of a negligible reaction hazard and relative brevity

The necessity of the re-treatment of previously treated maternal syphilis during pregnancy is now open to question [3] However, if a policy of treatment of such cases is adopted, penicillin in oil and wax in the schedule described above would appear to be a safe and satisfactory method of carrying out the treatment on an ambulatory basis The absence of syphilitic infants in 57 cases so treated compares favorably with all other treatment schedules for this

Although in the present study emphasis was not placed on the use of this treatment schedule in infectious or central nervous system syphilis, preliminary results would indicate that it is a satisfactory scheme for the treatment of these forms of syphilis if more orthodox penicillin schedules cannot be carried out

Summary

1 Forty-eight cases of early latent syphilis were treated with an intermittent ambulatory scheme of 600,000 units of penicillin in oil and wax twice a week for six weeks with concurrent dosage of 0 2 Gm of bismuth subsalicylate in oil once weekly for twelve weeks and followed for six months or more in the syphilis clinic of the New York Hospital Of the entire group, 72 per cent showed a sustained seroreversal, and 75 per cent of the remaining cases exhibited a drop in titer following treatment

2 The same treatment schedule administered to 57 cases of syphilis in pregnancy apparently provided adequate protection for the fetus, since no syphilitic infants resulted

THE MIGRAINE PROBLEM

ARNOLD P FRIEDMAN, M D , New York City

(From the Division of Neuropsychiatry, Montefiore Hospital, the Department of Neurology, College of Physicians and Surgeons, Columbia University, and the Neurological Institute)

THE most dramatic form of chronic headache is migraine The unique visual phenomena which so often precede an attack, the fact that the pain is usually limited to one side of the head, and the vomiting and general prostration which accompany most attacks have long made it an object of interest, and the literature on migraine is almost as great as that on all other types of headache combined

Although there is little reliable data concerning its frequency, estimates have been made that about 8 per cent of the population suffer from this type of headache Migraine often begins in childhood, and about half the cases report their first attack before fifteen years of age We have seen patients whose first attack started before five years of age and others whose headaches started after the age of sixty Women outnumber men in seeking relief in the disease but not to the extent reported in the literature About 60 per cent of the migraine cases report a history of migraine in their family

Physiology and Causative Factors

The underlying pathophysiology causing migraine is unknown A number of factors have been indicated However, it is quite clear that no single process or mechanism is responsible in all cases of migraine At the present time most investigators are in favor of explaining the prodromata, course, symptoms, signs, and sequelae of the disorder on the basis of changes in the cerebral and meningeal circulation.[1] Proponents of the vascular theory believe that an initial cerebral vasoconstriction of the cranial arteries produces visual and other preheadache phenomena This prodromal period is followed by the pain associated with the migraine attack which is caused by dilatation and distention of relaxed cranial arteries, primarily branches of the external carotid

Persistent vasodilatation of the cranial arteries results in a thickening of their walls and often in edema of surrounding tissues This causes the soft collapsible arteries to become rigid and pipelike and the pain to become a steady ache instead of the throbbing, pulsating type which is seen in its inception Secondary to such prolonged effects of pain and distention of the cranial arteries is contraction of the skeletal muscles of the head and neck This in itself becomes painful and adds a component to the migraine headache which may outlast the original vascular pain

Efforts to correlate biochemical changes in people suffering with migraine headaches have been unsatisfactory Studies on blood, urine spinal fluid, basal metabolic rate, etc , in most instances have failed to disclose any results which deviate significantly from the normal

The importance of psychologic factors in migraine has long been recognized Personality studies have indicated that many of these people are meticulous, neat in appearance, rigid in their thinking, and exceedingly aggressive toward their environment In their earlier life history, it is often noted that they have had considerable insecurity with resulting tensions which are manifested in inflexibility, overconscientiousness, meticulousness, perfectionism, and resentment [2]

It would seem from the reports of many authors and our own experience that emotional factors can be the trigger which sets off the migrainous attack [3] However, whether there is a specific personality type which suffers from migraine is still a moot question. Most of the cases which we have studied reveal unusual ambition, aggressiveness, exactness, and hostility

Psychologic investigations, such as Rorschach studies, tend to bear out the clinical impression, i.e rigidity, perfectionism, etc , regarding the personality features in these people [4]

Symptoms

A most extraordinary feature of the migraine syndrome is the fact that it is not limited to the head but may manifest itself in widespread disorganization of bodily function such as visual disturbances, gastrointestinal disturbances, etc

The attacks themselves are featured by their periodicity and head pain, which is unilateral at the onset, most often throbbing in character, and are associated with nausea, vomiting, photophobia, and mood changes The headaches may be preceded by visual symptoms such as scotomas, diplopia or hemianopia, gastric disturbances, and paresthesias The head pain may be localized to any site of the head, face, or neck but is most often reported in the orbital, frontal, and temporal regions The duration of the attacks may vary from minutes to days They commonly occur in relation to a let-down period such as week ends, holidays, or social engagements Disarrangement of other bodily

functions are numerous, vertigo, chilliness, edema, tremor, abdominal pain and distention, diarrhea, polyuria, pains in the extremities, and marked mood disturbances may be associated with the headache or in some cases may act as migraine equivalents

In summarizing such a clinical picture, it becomes evident that we are dealing with individuals who have a labile physiologic mechanism which makes them sensitive to any emotional stress During these states such labile mechanism can set off multiple physiologic reactions which we call the migraine syndrome, the headache itself being the most prominent symptom in a widespread pattern of dysfunction

Due to the variability of these attacks, many names have been attached to these episodes, such as menstrual headache, week-end headache, menopausal headache, constipation headache, histamine headache, and atypical facial neuralgia

Diagnosis

The diagnosis of the underlying cause of headache, or in this case migraine headache, in every patient requires careful physical and neurologic examination with ancillary tests such as roentgenologic examination, electroencephalogram, and any other laboratory studies which may be indicated However, it is just as important that the patient be studied adequately from the psychologic point of view because headache, particularly chronic headache, is truly a psychosomatic problem, and neither the physical nor the psychologic aspects can be neglected when one is attempting to formulate a diagnosis of this symptom

The diagnosis of migraine headache is based essentially on the clinical history Riley and his associates found that routine methods of laboratory investigations of patients suffering from migraine do not supply any information of positive diagnostic value [5]

Engel and his associates were the first to detect that electroencephalographic changes may accompany visual scotoma preceding migraine headache [6] However, during the attack of migraine there has been little change in the electroencephalographic records

It is important to distinguish migraine from similar symptoms which occur on some other basis Tumors, particularly angiomas which most often appear in the parietal-occipital region, may lead to attacks of headache, nausea, and vomiting, sometimes associated with visual hallucinations In these cases, careful perimetry usually shows a visual field defect which persists between the attacks Often convulsive seizures are part of this picture, and sooner or later intracranial pressure may develop as the tumor exerts pressure or encroaches upon neighboring parts of the brain Sometimes in the case of angioma a cranial bruit may be heard Migraine may simulate or be simulated by an aneurysm of the internal carotid artery which presses on a nerve In these cases attacks of visual disturbance, preceded by scotomata, may occur in the affected eyes together with headache Persistent field defect and reduction of visual acuity or extraocular palsies may be associated with other focal signs in the case of the aneurysm

Migraine is confused with epilepsy occasionally since visual hallucinations may constitute the prodromal symptoms of both The loss of consciousness, the rapidity of the attack, and the clinical description all are used in differentiating between these syndromes

Transitory attacks of paresthesia, weakness, and aphasia may occur in migraine without headache Differentiation of this from disseminated sclerosis or cerebral vascular lesions may at times be difficult However, history and neurologic examinations usually reveal findings which differentiate these conditions

Of course, headache occurring alone must be distinguished from pain in the head due to other causes In such headaches we must distinguish the various neuralgias, neuritides, diseases of the bones of the cranium, meningeal irritation, fibromyositis, etc

Headache associated with temporal arteritis may occasionally be confused with migraine [7] This condition usually occurs late in life, and the arteries in the temporal fossa become distinctly palpable during the time of headache The lesion is thought by some to be one of chronic periarteritis

People who have migraine headaches may occasionally develop cerebral or subarachnoid hemorrhage and thrombosis The changes in the caliber of the intracranial vessels, although abbreviated, may lead to permanent changes in their walls and the precipitation of vascular insults In some cases, relaxation of the vessel walls, often associated with hypertension, results in hemorrhage and in others results in severe spasm leading to thrombosis We have seen migraine associated with or develop in individuals who suffer from hypertension, multiple myeloma, Paget's disease, tuberculosis, Raynaud's disease, Ménière's disease, and rheumatic fever

Treatment

In approaching the therapeutic problem posed by the headache patient, the physician has four main methods which can be used individually or in any combination pharmacotherapy, psychotherapy, physiotherapy, and surgery He may attempt either to afford the patient symptomatic

relief or to prevent the occurrence of a headache entirely The latter is obviously the preferable result if it is attainable, but most of our therapy today falls short of this goal

The number of therapeutic agents which have been used in the treatment of these patients indicates the unsatisfactory state of our knowledge Many reports have been made which hailed brilliant results for some new therapeutic agent, but it seems that these treatments are only successful in the hands of the individual therapist With the exception of the ergot derivatives, which are valuable only in the symptomatic treatment of an attack, no one has as yet reported any medication which will cure migraine

In attempting to prevent the occurrence of headache entirely, several forms of therapy have been tried The problem has been approached surgically by removing various sympathetic ganglia, dividing meningeal and temporal arteries, and in some cases by cutting various nerves such as the greater superficial petrosal, etc Medically, such forms of therapy as thiocyanate, histamine, special diets, vitamin therapy, and desensitization to various allergens have all been tried with little success

It is well known that suitable psychotherapy may be of great value in reducing the intensity and frequency of migraine attacks and may even result in their disappearance for a considerable time We should emphasize that there is a large group of these patients who will respond satisfactorily to the type of psychotherapy which is well within the province of the general practitioner

The treatment of an individual attack of migraine (symptomatic treatment) as opposed to a type of treatment which prevents the occurrence of headaches entirely (prophylactic) is essentially one of pharmacotherapy We have tested a number of drugs in the symptomatic treatment of migraine in an effort to evaluate their relative efficacy The drugs we have used fall into four main groups vasoconstrictors, vasodilators, sedatives, and analgesics In testing these various drugs we concluded that ergotamine and its derivatives are distinctly superior in therapeutic efficacy to all other types of drugs [5] These reports are in accord with current opinion that ergotamine and its derivatives are unequalled in the symptomatic treatment of migraine

The clinical observation of the beneficial effects of ergotamine tartrate on the migraine headache has been confirmed by experimental evidence in the laboratory In the migraine attack the intensity of the pain closely parallels the amplitude of pulsations of the branches of the carotid vessels The therapeutic effect of ergotamine tartrate depends on its ability to produce prolonged vasoconstrictor action This has been demonstrated by direct observation on and photography of branches of the external carotid We have demonstrated by arteriography a similar vasoconstrictor effect of the drug on the internal carotid artery Other vasoconstrictor agents, such as pituitrin, ephedrine, dexedrine, and epinephrine, are not constant in their degree of vasoconstriction or duration of action and cannot be counted upon for therapeutic use

The results obtained by the use of ergotamine and its derivatives are still far from perfect, even when care is taken to give an adequate dose as early as possible after the onset of symptoms (Table 1) The results can be improved by having the patients who are not relieved after oral administration of the drug receive it by injection instead But this procedure again does not insure certain relief, and it has the drawbacks of technical difficulty, on the one hand, and an increase of the incidence of unpleasant side-effects, nausea and vomiting, on the other

TABLE 1.—EFFECTIVENESS OF VARIOUS DRUGS IN RELIEVING MIGRAINE ATTACKS IN 94 PATIENTS

Drug Types	Good Relief	Fair Relief	No Relief	Total Number of Trials
Ergotamine and derivatives	53%	20%	27%	161
Vasodilators	13%	22%	65%	31
Analgesics	21%	23%	56%	53

In the hope of improving the results obtained from ergotamine, we tried two modifications in the mode of administration first, it was administered in a rectal insert in combination with atropine, and second, it was given orally in combination with caffeine [8] We also used dihydroergotamine methanesulfonate (DHE-45), which has been reported to be more efficacious than ergotamine itself in relieving migraine attacks

By treating a number of patients with each of the drugs mentioned above for a long period of time to be sure of the degree of relief which each drug afforded, we were able to compare the efficacy of each of the various preparations which was used in turn on the same subject It appears that best results have been obtained by the combination of ergotamine and caffeine (cafergone) orally and by the use of rectal inserts containing ergotamine and atropine (Table 2) There is no apparent difference between the efficiency of these two preparations, and both seem distinctly superior to ergotamine tartrate by mouth and DHE-45 (dihydroergotamine methanesulfonate) by mouth

For parenteral use dihydroergotamine methanesulfonate (DHE-45) is the medication of choice in the treatment of migraine It is from

TABLE 2.—Cross Comparisons of the Efficacy of Several Drugs in the Treatment of Migraine

	Ergotamine Tartrate Superior	No Difference Noted	Ergotamine Tartrate Inferior
Ergotamine and caffeine	10%	35%	55%
DHE-45	25%	25%	50%
Rectal inserts	18%	18%	64%
	Rectal Inserts Superior	No Difference Noted	Rectal Inserts Inferior
Ergotamine and caffeine	31%	38%	31%
DHE-45	57%	43%	0
	DHE-45 Superior	No Difference Noted	DHE-45 Inferior
Ergotamine and caffeine	13%	27%	60%

five to ten times less toxic than ergotamine tartrate and should be given in doses at least twice as great as ergotamine tartrate

Summary

The mechanism which best explains the prodromata, course, signs, and sequelae of a migraine headache is one of changes in the cranial circulation Dilatation and distention of relaxed cranial arteries, primarily branches of the external carotid, cause the pain associated with the migraine attack

Personality traits of the migraine patient are unusual meticulousness, ambition, aggressiveness, exactness, and hostility toward their environment Such character traits lead to emotional tension which sets off widespread somatic disorganization of which the headache itself is the most prominent symptom

Diagnosis of migraine headache is essentially one of clinical history However, it is important to distinguish migraine from similar symptoms which occur on some other basis (i e tumor, aneurysm)

Symptomatic treatment of the migraine attack is essentially one of pharmacotherapy, and our best results have been obtained by use of ergotamine tartrate with caffeine orally or administered in combination with atropine

The present status of the migraine problem can be summarized by stating that we have reached a point in the therapy where in most cases the practitioner can modify the frequency and severity of the patient's headache However, complete therapeutic success with this tenacious symptom is something for the future

HEALTH PROGRAM FOR SCHOOLS

Stating that the health of New York City's high-school students is far below par, Mr Anthony Campagna, member of the Board of Education of New York, outlined a five-point health program for the city's secondary schools, at the annual meeting and election of officers of the Bronx Tuberculosis and Health Committee, held April 27

Mr Campagna, in urging all voluntary health agencies in every borough to support the Board of Education in its current efforts to improve the health of teen-agers, cited the "distressing fact" that of all the high-school graduates who, in September, 1948, applied for admission to the New York State Maritime Academy at Fort Schuyler, the Bronx, 50 per cent had to be rejected because of physical defects, of which a majority were correctable.

Re-elected as chairman of the committee, which is a part of the New York Tuberculosis and Health Association, was Dr Nathan B Van Etten

In his report to the committee, Dr Van Etten stated that 9,119 chest x-rays had been taken by the committee during the past year and that 2,783 families and individuals had been aided with their health problems More than 50,000 persons, he said, had attended meetings, lectures, motion picture showings, and exhibits held under committee auspicies. During the year 3,842 parochial school pupils had received audiometer tests

Case Reports

CENTRAL PLACENTA PREVIA WITH MISSED LABOR

MARY JANE BIRD, M D , and HAROLD S NEMSER, M D , New York City

(*From the French Hospital*)

A CASE is reported of a multiparous patient with intrauterine death of the fetus at term, retention of the infant for seven weeks, and its expulsion through a central placenta previa.

Case Report

A forty-year-old Puerto Rican registered at the French Hospital antepartum clinic in the fourth month of her fifth pregnancy Her past history was noncontributory Full-term pregnancies in 1931, 1934, and 1935 were uncomplicated with spontaneous deliveries following short labors in each case In 1935, she had an induced abortion in the second month of gestation

Her last menstrual period occurred September 8, 1944, making the expected date of confinement June 15, 1945 Menses had always been regular with an interval of thirty days At the time of registration (January 31, 1945), physical examination was unremarkable An ample gynecoid pelvis was noted with the size of the uterus corresponding to the period of amenorrhea Wassermann and Kline tests were negative Blood group was O, Rh positive Hemoglobin was 88 per cent

During subsequent clinic visits, the pregnancy seemed to proceed normally On May 20, one month before the estimated date of confinement, the patient was admitted to the hospital because of two days of painless vaginal bleeding with the passage of a few clots While in the hospital, she had a sudden gush of blood, amounting to about 500 cc At that time, the estimated fetal weight was 3½ pounds The fetal heart tones were of good quality The impression was that of possible placenta previa. Four days later, after cessation of bleeding, a vaginal examination revealed a firm external os that admitted a fingertip The cervical canal was 2 cm in length, and no placenta could be felt through it The patient was then discharged to the prenatal clinic

The pregnancy progressed uneventfully without further bleeding When seen in clinic on July 26, the patient's weight was 155½ pounds, 35½ pounds more than at the onset of pregnancy The baby was active At her next visit, August 15, she reported that the baby had not moved for two weeks There had been ten pounds weight loss during the preceding three weeks No fetal heart could be heard, and the uterus was irritable On August 27, abdominal palpation revealed crepitus of the skull bones A diagnosis of fetal death was made, and it was decided to await spontaneous onset of labor

The patient visited the outpatient department until September 19, at which time her weight was 137¾ pounds, eighteen pounds less than on July 26, when activity of the baby was last noted For two weeks she had had intermittent low abdominal and back pain At this examination, the uterus was the size of a seven or eight months pregnancy It was persistently tense, so that the presentation could not be determined. An x-ray demonstrated a dead fetus at term in left occipitoanterior position (Fig 1)

The patient was thought to be in early labor The first stage was desultory, lasting nineteen hours, with irregular lower abdominal pains and a continuous backache Throughout the first stage the uterus remained tense, and at no time was there any bleeding Caput was seen one hour after full dilatation The patient bore down well with her contractions, and the head delivered easily In spite of moderate traction on the head, the shoulders

FIG 1 Anteroposterior x-ray showing full-term fetus and central placenta previa.

could not be released The patient was then anesthetized, the posterior arm extracted manually, and the baby delivered after a two-hour second stage The child was a macerated 7 pound 2 ounce male

One-half cubic centimeter of pitocin was administered intramuscularly, and a gush of blood and amniotic fluid signalled the apparent separation of the placenta The uterus failed to contract under massage, and its flabby consistency was in marked contrast to its previous tonicity A small steady stream of blood flowed from the uterus The placenta was found to be in the lower uterine segment, still partially adherent A cleavage plane was readily found posteriorly, and a manual extraction was done The uterus contracted well after intravenous ergotrate Estimated blood loss was 200 cc The mother left the delivery room in good condition and had an uneventful postpartum course

Discussion

The fetus was delivered September 20 It was last known to be alive at the July 26 clinic visit The mother reported its death August 1 The x-ray demonstrates the distal epiphysis of the femur and the proximal epiphysis of the tibia, which suggests that the fetus was at term According to the patient's calculation, she was forty-six weeks pregnant at the time of fetal death Allowing a miscalculation of one month, the period of gestation was forty-two weeks

The placenta was found to be funnel-shaped with a slit, 8 cm. in length at its apex, through which the fetus had passed (Fig 2) The placenta was markedly attenuated and fibrotic. The greatest distance from the central slit to the margin was 16 cm , the least 14 cm. Its thickness was nowhere greater than 1 cm The membranes attached to the broad base of the cone also exhibited degenerative changes From its conical shape, it is obvious that the placenta could have been implanted only directly at the fundus or over the internal os, i e , central placenta previa. During the vaginal examination in May, one month before the estimated date of confinement, the placenta was not recognized because the layer of placental tissue was so thin and because cervical dilatation was insufficient to allow adequate examination The abdominal film helps to confirm the diagnosis of central placenta previa (Fig 1) A conical shadow can be seen over the internal os and extending over about one half of the inner surface of the uterus. This shadow corresponds to an x-ray that was taken of the placenta after its fixation in formalin

It may then be assumed that the fetus died at forty-two weeks gestation and was retained in utero for seven weeks before its spontaneous expulsion through a fibrosed central placenta previa.

FIG 2 Fibrotic, attenuated placenta showing slit at its center through which fetus passed.

LICENSURE OF ALL NURSES NOW MANDATORY

The New York Nurse Practice Act of 1938 which provides for mandatory licensing of all who nurse for hire became effective April 1 This act includes both the registered and the practical nurse classifications

While all states have licensing laws, licensure for both registered and practical nurses was mandatory heretofore only in Arkansas and Hawaii Thus New York State is among the first to pass this type of legislation. The New York State Nurses Association has been striving for years to activate this law, which is designed to protect those who employ nurses The act may also help to alleviate the nurse shortage since it provides for licensing, without further examination, of many out-of-state nurses who meet minimum requirements.

The State Education Department has processed more than 30,000 applications for licenses from both practical and registered nurses, many of whom were practicing within this State without a New York license

The Association urges that those who employ nurses to serve in private homes require evidence of licensure as a protection against those who misrepresent themselves as "trained nurses." This law does not prohibit care of the sick by relatives, friends or housekeepers —*Health News, April, 1949*

FOREIGN BODY (NEEDLE) IN HEART

JACKSON H FRIEDLANDER, M D , HAROLD R BRODMAN, M D , and CHARLES E SMITH, M D , Northport, New York

(*From the Medical Service of Northport Veterans Administration Hospital*)

TRAUMA to the heart has been the subject of numerous reports, chiefly from the viewpoint of the surgeon. Elkin reviewed the general problem of wounds of the heart and stated that the electrocardiogram was of little use in establishing a diagnosis, since normal tracings may be obtained for several hours after injury [1] He did believe they were of use in determining the extent and progress of infarction after wound repair Most of the wounds discussed were knife wounds

Porter and Bigger described two cases of stab *wounds of the ventricle* [2] *The electrocardiographic* change of coronary thrombosis was believed due, in one case, to the severing of a branch of the left coronary artery and in the other to an area of ischemia caused by the repair of the wound As an interesting sidelight they noted the absence of pain in both cases and offered the explanation that, since the muscle fibers were severed, there could be no accumulation of pain-producing metabolites due to ischemia, because the fibers could not contract and hence would accumulate no metabolites

Another type of injury, described by Shapiro, was that of a hollow needle entering the heart via the venous blood stream, and a case similar to the one reported here was presented by Fair, who reviewed the literature of needle injuries to the heart [3,4] Unfortunately, no electrocardiograms were obtained on this case

The following is a case of trauma from a self-inflicted needle in the heart, complicated by a retrocardiac accumulation of pus or blood

Case Report

The patient was a thirty-four-year-old white man admitted on February 8, 1946, with a diagnosis of hebephrenic dementia precox On admission the patient was placed on special observation group because of continued expression of self-destructive ideas His physical examination revealed no objective findings other than an electrocardiogram which was suggestive of some myocardial impairment During his stay in the hospital he inflicted several puncture wounds with any object obtainable that was suitable for the purpose, such as the staples which bind magazines These he removed, straightened, and inserted into his abdominal wall with no subsequent complications

On May 13, 1948, at midnight, the patient was found in bed, comatose, skin cold and clammy, with pulse not perceptible and heart sounds scarcely audible Breathing was labored, and patient was cyanotic He was transferred to the medical service where he was placed in an oxygen tent and treated for shock

Physical examination revealed the patient to be in profound shock with blood pressure unobtainable

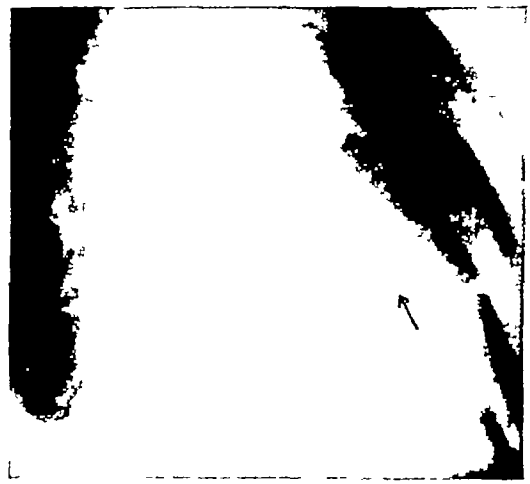

FIG 1 Rotation toward left posterior oblique (15 to 20 degrees)

There was a small, round, indurated area about 2 5 cm in diameter at the fourth left intercostal space in the midclavicular line which appeared to be tender, since patient responded somewhat to palpation in this area Closer inspection revealed what was interpreted as the site of a pinprick at the second left intercostal space, 3 5 cm lateral to the left

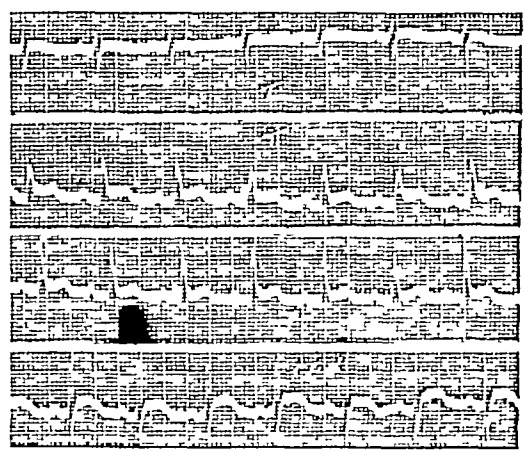

FIG 2 Tracing taken at 10 00 A.M. May 14 about ten hours after insertion of needle and prior to removal Tendency to right axis deviation was present previously, QRS is slurred and notched in leads 2 and 3, and there is an elevated ST segment in these leads ST segment shift is due to current of injury probably caused by subepicardial damage.

Published with permission of the Chief Medical Director Department of Medicine and Surgery Veterans Administration who does not assume responsibility for the opinions expressed or conclusions drawn by the authors.

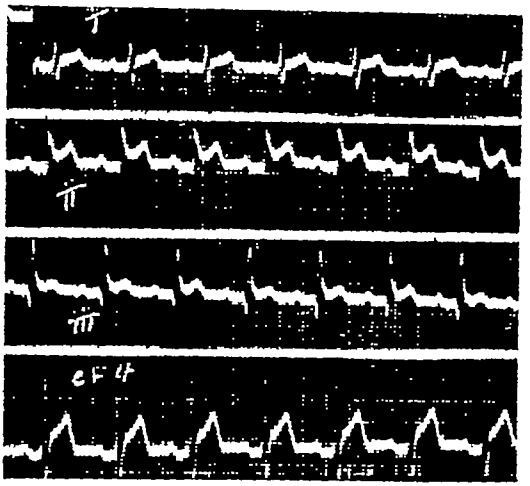

FIG 3 Taken at 2 00 P M May 14 immediately following removal of needle There is further upward displacement of ST segments in leads 2 and 3 and the appearance of a Q_3 changes seen in the evolution of a posterior wall infarction However, in CF_4 there is an elevation of the ST segment.

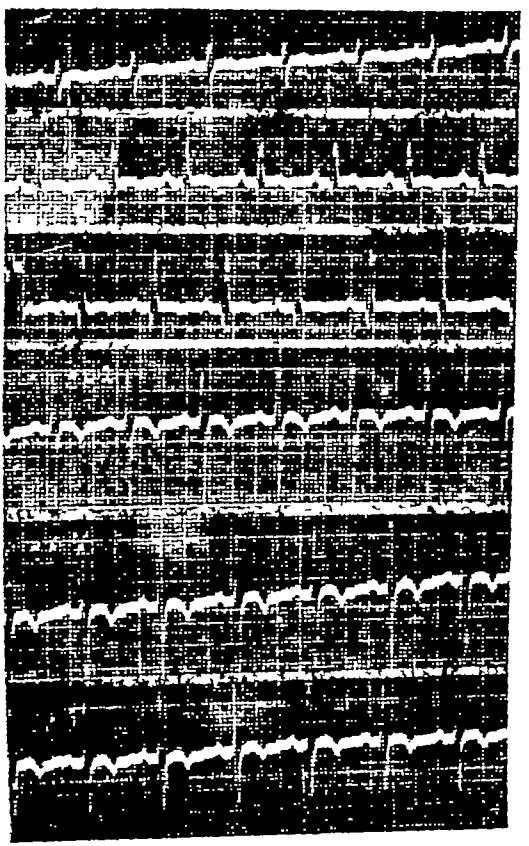

FIG 4. Electrocardiogram taken June 7 T is inverted in all leads This is the time when the retrocardiac mass was most prominent T waves in chest leads became upright when the mass resolved

FIG 5 (Top) Posteroanterior view of chest taken on June 9 showing shadow of posterior mediastinal mass protruding beyond left heart border (Bottom) Lateral view showing more clearly the globular mass behind the heart

parasternal line Bedside x-rays of the precordium disclosed the presence of a large needle which appeared to be in the heart musculature (Fig 1) An initial electrocardiogram showed ST segment changes in leads 2, 3, and CF 4 (Fig 2)

The patient responded gradually to treatment and on the next day an incision was made in the left fourth interspace about 1 5 cm lateral to the sternal border The eye of the needle was encountered at a depth of 1 cm Motion of the needle could be felt with the palpating finger which was synchronous with the heart beat The needle was grasped with a clamp and extracted Serial electrocardiograms were taken with the needle in situ and for several days after removal (Figs 3, 4)

The patient's postoperative course was very stormy He ran a septic temperature for several weeks despite adequate chemotherapy and penicillin Repeated x-rays of the chest in the oblique

and lateral positions showed a rapidly increasing globular mass in the posterior mediastinum, just behind and to the left of the heart This was interpreted as a mediastinal abscess or encapsulated blood (Fig 5) Attempts at aspiration of this mass were unsuccessful However, the temperature slowly fell to normal, and the mass gradually resolved It was concluded that the mass was probably blood rather than an abscess, since it resolved completely in a short time The patient at the present time is up and about the ward with no complaints

Summary

A case is presented of a foreign body (needle) in the myocardium, with recovery following surgical removal of the needle Serial electrocardiograms were obtained prior to and after removal of the needle The electrocardiographic changes suggested initially an acute pericarditis with subsequent changes resembling those of a posterior wall infarction and finally an atypical picture of the limb leads showing changes of posterior wall infarction and the chest leads showing inversion of all T waves

LOCALIZATION OF METASTATIC CANCER BY TRAUMA

George T Pack, M D , and Robert J Booher, M D , New York City

THE influence of trauma on the occurrence and spread of tumors is quite widely discussed and litigated Recent experiments in attempting to localize tumor metastases in long bones by mechanical trauma have recalled a most unusual case history which bears on the problem and illustrates similar conditions occurring in the management of cancer in man It is of such timely bearing, in the light of these experiments, that we wish to record it for general discussion of this problem.

Saphir, Appel, and Levinthal have reported a series of experiments designed to study the effects of a single mechanical trauma and of chronic irritation in the localization of metastases of the Brown-Pearce carcinoma in long bones of male rabbits [1] They report three series of studies, using the Brown-Pearce rabbit tumor which is highly malignant and which can be readily transplanted into the testes, from which it metastasizes early from the time of intratesticular transplantation and produces a generalized carcinomatosis. In the first of this series of experiments, the humerus was fractured and immediately afterward an injection of tumor cells was made in an ear vein In the second series, the humerus was fractured, and fourteen days later the suspension of tumor cells was injected in the ear vein, and last, in the third series, the tumor was transplanted into the testes and, two weeks later, the humerus was fractured In none of these animals was there roentgenographic, macroscopic, or microscopic evidence of tumor formation at the site of fracture, although autopsy disclosed metastases in various organs The results of these experiments were summarized to show that mechanical trauma, or chronic irritation of bones, played no role in the localization of metastases from transplanted Brown-Pearce carcinomas in rabbits

In view of these experiments, the following case history is most interesting

Case Report

L D was a thirty-four-year-old white man whose chief complaint was difficulty in breathing through the left nostril for the two years preceding his report to a tumor clinic At the time of his initial visit he stated that he had been treated by endotherm-snare excisions and various surgical and medical treatments for his nasal obstruction without relief He occasionally had epistaxis and sometimes an infection in the posterior nares with considerable febrile reaction

Physical examination revealed a pale, anemic young man. In the left nares there was a granular, polypoid lesion which was infected and bled easily on being traumatized with the probe The mass occluded the posterior nares There was no tributary adenopathy in either the submaxillary or the deep cervical lymph node regions on either side The remainder of the examination was that of an essentially normal male of thirty-four years of age A presumptive diagnosis of carcinoma of Schneiderian membrane type was made without palpable involvement of lymph nodes This lesion was biopsied, and the report of Doctor A. Hobson Davis, the pathologist, was "rapidly growing malignant tumor, probably of transitional cell type This tumor is frequently called 'lymphoepithelioma' "

Radiation Treatment.—A course of high voltage x-ray therapy was then prescribed, using two portals on either side of the face, cross-firing at the nose and nasopharynx The following factors were used 200 kilovolts, 0 5 mm copper-aluminum filtration, using a 5-cm cone at 60-cm. skin target distance, giving 300 roentgen fractions each day to alternate portals until a total dose of 2,400 r × 2 was given

The lesion responded rapidly, and, before 900 roentgen units had been delivered to each portal

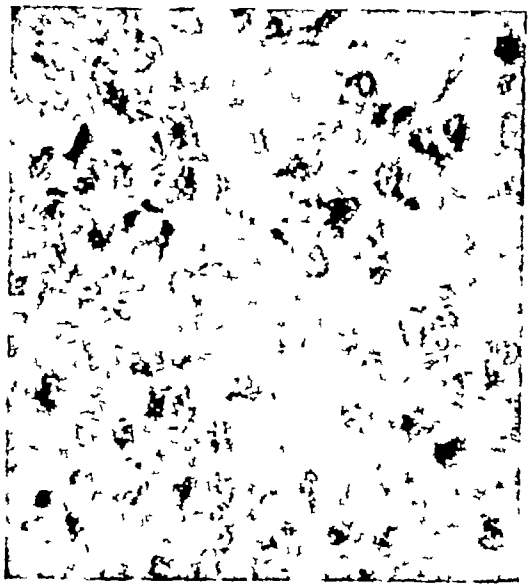

FIG 1 Primary nasopharyngeal tumor

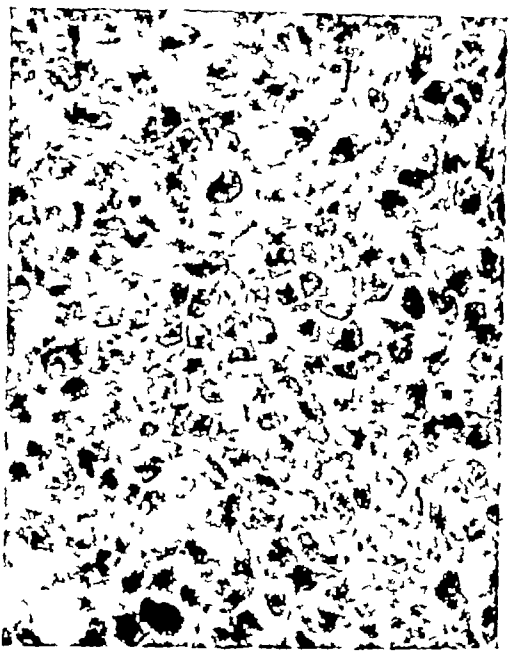

FIG 2 Metastatic tumor involving shaft of penis. Note identical histologic structure

the patient was able to breath through the left side of his nose for the first time in two years, a finding confirming the radiosensitivity of the tumor As the mass subsided, its origin from the septum could be demonstrated The x-ray treatment was given within a period of eighteen days This produced a brisk reaction in skin and nasal mucosa and clinical disappearance of the lesion It was then thought best to supplement the irradiation with a tandem of two heavily filtered radium capsules Accordingly, 14 platinum cells containing 3 33 mg each of radium were inserted in a tandem of two capsules The filtration equivalent of 1 mm of platinum was used with seven cells being used in each capsule These were placed in the posterior left nares until a total dose of 1,000 mg hours was given in the course of twenty-one and one-half hours time The lesion had completely healed within three months, and there was no evidence of metastasis to regional lymph nodes

Nature of Accident.—Twenty-one months after the institution of treatment for the cancer of his nasal septum, he sustained an unusual injury to his penis The injury amounted to one which produced a fracture of the erect organ It occurred during sexual play in which he was seated while nude in a chair and his girl companion threw herself unexpectedly onto his lap It was attended with severe pain, ecchymosis, and swelling, which subsided in time with conservative measures Approximately two weeks after this trauma, a nodule appeared at the site of the injury on the left side of the shaft of the penis and grew rapidly in size It was not attendant by pain or tenderness, but there was occasional chordee Four weeks elapsed after the trauma before he reported for examination He then presented a tumor on the dorsum of the penis, measuring approximately 5 cm. in diameter, which was encapsulated entirely in the left corpus cavernosum

Treatment of Metastasis to Penis —Due to the history of trauma, the presumptive diagnosis was unresolved hematoma, subsequent to a so-called fracture of the penis He was referred to Dr Benjamin Barringer at the Memorial Hospital At the time of his examination on December 8, 1936, the patient presented a swelling which was attached to the corpus cavernosus of the penis and measured approximately $2\frac{1}{2}$ by $1\frac{1}{2}$ inches With the *tentative diagnosis of hematoma or organized blood* clot of the penis, an operation for excision of the mass was performed. After exposing this lesion, it was found to be approximately 3 cm in diameter and was situated on the dorsal aspect of the lower third of the penis It seemed to be made up of an overgrowth of tissue of the corpus cavernosum, but in one region the tissue was of softer consistency, slightly grayish in color, and with the general appearance of a sarcoma An attempt was made to perform a complete excision of this mass, but because of almost total involvement of this portion of the corpus cavernosum, it was almost impossible to remove it At one place, it was adherent to the urethra itself, and in excising this segment a portion of the urethra had to be removed A catheter was inserted into the urethra and layer closure effected

Pathologist's Report.—The pathologic specimen was reported as follows "Oval mass of soft tissue measuring 6 by 5 by 4 cm and one small loose fragment of skin, which measures 3 by 1 cm" It appears to represent a portion of the penis which has been completely infiltrated by tumor, except for one small portion of the corpus spongiosum The tumor has ulcerated into the urethra. On section, the tumor presents an opaque, grayish-white, glistening surface The loose fragments of skin contain on the

under surface two small tags of tumor tissue Microscopic diagnosis "malignant tumor—resembles reticulum cell lymphosarcoma"

Subsequent Course.—The patient was discharged on the day after the operative procedure, and although the wound was slow in healing due to a transitory urethral fistula, it had healed completely within four weeks High voltage irradiation was given to the lesion with the following factors 200 kilovolts, 0 5 mm. copper filtration, 50 cm skin target distance, 25 ma , 3 8 minutes, and 200 r daily, a total dose of 1,000 r

The infected nasal cavity gradually responded to local measures, although several pieces of maxilla were exposed. Another débridement was done at which time two small fragments of tissue, measuring about 2 cm in diameter, were obtained. These appeared to be neoplastic tissue, and the report by Dr F R. Sandt, the pathologist, was recurrent transitional cell carcinoma At this time, necrosis was quite extensive and a perforation had appeared through the hard palate Wide débridement was done. A blood transfusion was then given without reaction. The patient's subsequent course soon became critical, and he died twenty-seven months after his initial examination and six months after the metastatic deposit in his penis

Final Opinion of Pathologist.—The various tumor specimens have been examined subsequently, and it is the opinion of Dr A. Hobson Davis that the lesion originally biopsied in the nose, as well as the recurrent lesion found in March of 1937, and also the tumor of the penis, all are identical neoplastic tissue, which he believes represents transitional cell carcinoma. The opinion of Dr Frank Foote is that the lesions are indeed similar and are most probably reticulum cell lymphosarcoma (Figs 1 and 2)

Comment

Metastatic involvement of the penis by cancer from a distant site is of extremely rare occurrence At the time it made its recognizable appearance in this patient, there were no evidences elsewhere of metastatic deposits of cancer and no clinical proof of local recurrence in the naris It would seem strangely coincidental that this young man could have had a metastatic lesion in the penis prior to the injury and unknown to him and that the presence of the metastasis predisposed the organ to injury after the manner of traumatic determinism. The trauma sustained was bona fide and of major character The time elapsing between the date of the injury and the growth of the metastatic tumor was less than one month The site of the trauma and the localization of the secondary tumor were the same Pathologists agree that the penile neoplasm and the one in the nose were of identical histogenesis These facts would seem to fulfill all the postulates concerning traumatic relationship Theoretically the cancer cells must have been in the blood stream at or shortly after the penile injury, in order to be deposited there and find proper soil in which to develop

PENICILLIN DISCOVERER PRAISES FREEDOM IN RESEARCH

Sir Alexander Fleming, the discoverer of penicillin, dedicated the Oklahoma Medical Research Foundation on July 2 to the proposition that great discoveries most often were made by research men left free to follow the leads provided by chance or luck in the scientific laboratory

Sir Alexander's experience, which led to the development of modern disease-killing drugs, is frequently cited as an outstanding example of the importance of serendipity in science He found penicillin by chance but had been trained to look for significance in scientific "accidents"

He spoke in Oklahoma City on a program celebrating the opening of a new research project that has attracted nation-wide attention—it was financed by the voluntary contributions of 7,500 Oklahomans who have pledged a total of $2,400,000 for research

Most medical research centers are supported by government funds, large gifts from philanthropists, or industrial grants Oklahomans paid for this one the largest contribution was $26,000 from an oil man, and the smallest was 30 cents. Sir Alexander congratulated the citizens of the state for the public interest in medical progress which this response proved He promised that the laboratory may "prove a thousand times more valuable to humanity than all the oil in Oklahoma"

Then he warned the new foundation's directors to choose well-trained researchers and allow them complete freedom to explore the unknown country of the "sick man"

"You do not know what you will find," Dr Fleming said, "you may set out to find one thing and end up by discovering something entirely different

"This type of research cannot be controlled We can plan some aspects of medical research, but we cannot plan pure fundamental research any more than we can organize developments in art or literature

"We cannot plan genius, but it is up to the rulers of a foundation such as this to create the free atmosphere which will allow genius full play," he said

DIAPHRAGMATIC HERNIA THROUGH THE FORAMEN OF MORGAGNI

WILLIAM W JOHNSON, M D , F A C S , Plattsburg, New York

(*From the Physicians Hospital*)

DIAPHRAGMATIC hernia is a condition not infrequently recognized by present-day methods of diagnostic procedure Proved cases of such hernia passing through the foramen of Morgagni are still a rarity Justification for the report of a single case is based on the thoughts that (1) it is well to keep the possibility of such a condition in mind, (2) the diagnosis in this instance was made by exceptionally definite x-ray evidence, and (3) proved cases are still uncommon

In 1930 Hedblom collected from the literature and reported 56 cases of this type of diaphragmatic hernia These were not all proved cases, and the author himself questions the diagnosis in some of them [1] A review of the literature from 1930 to 1941 by Harrington produced reports on 24 additional cases [2] In 1945, Harrington reported that, in 404 operative procedures he had performed for diaphragmatic hernia, only eight were of the subcostosternal variety [3]

Case Report

E C , a white woman, age twenty-six, was first seen in April, 1947 She complained of a chronic cough and general ill health She had been troubled by "gas" in her stomach and cramps for a long period of time, which had made her an invalid, and, therefore, she had been unable to get or retain any remunerative occupation since she had graduated from high school One year previous, a tumor was removed from the right breast with no relief of symptoms

She still complained of mild epigastric pains, characteristically crampy, often associated with nausea but rarely with emesis The symptoms were unrelated to meals or to type of food Symptoms were intermittent, lasting for a few days, then disappearing For the past two months there had been increasing cough and moderate expectoration

The patient was referred to the Ray Brook Clinic for examination At the clinic no abnormal chest findings were observed on examination There was a well-healed scar in the inner lower quadrant of the right breast There were no nodules in the scar and no axillary, supraclavicular, or cervical nodes The abdomen was negative

Sputum specimens revealed no acid-fast bacilli when examined by the concentration method Two tuberculin tests with 0 1 and with 1 0 mg of old tuberculin were negative

X-ray films of the chest taken on May 22, 1947, showed a triangular dense shadow lying just above the diaphragm in the medial and anterior aspect of the lung field just against the shadow of the heart

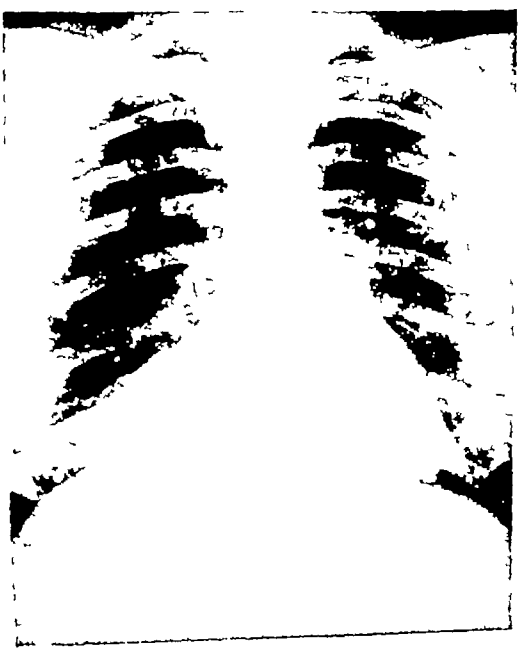

FIG 1 Posteroanterior film of chest shows dense shadow beside the right heart border

FIG 2 Anteroposterior film of abdomen and chest five hours after ingestion of barium. The colon is seen rising above the right diaphram and lying against the right border of the heart.

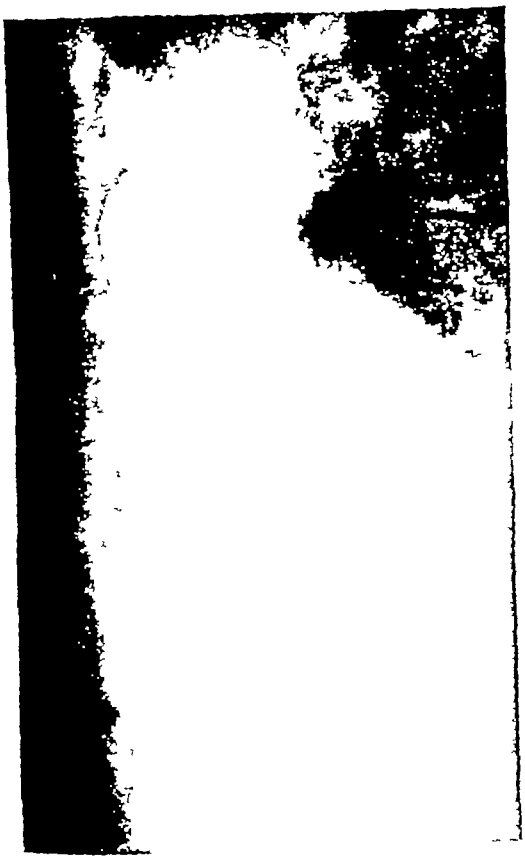

FIG 3 Lateral film of abdomen and chest five hours after ingestion of barium The colon is shown lying in the anterior chest.

on the right side In the upper portion of this shadow there was an irregular area of decreased density (Fig 1)

On June 25, 1947, a gastrointestinal series was done. On fluoroscopic examination it was noted that the density in the right lower anterior chest moved upward when the patient sniffed, while the diaphragm moved normally downward The gastrointestinal series was negative until one and a half hours when it was noted that the head of the meal was in the ascending colon and that there was a large gas bubble in the lower medial anterior portion of the right chest This definitely demonstrated the presence of bowel in the chest From three to five hour x-rays showed the ascending colon to turn medially and overlie the second lumbar vertebra It coursed up the spine to the level of the twelfth dorsal, then extended somewhat laterally and upward to pass the outline of the diaphragm at the level of the eleventh dorsal vertebra. It extended laterally to about the midchest, upward to the level of the ninth rib posteriorly, medially to the right side of the spine, downward to the level of the eleventh dorsal vertebra where it again crossed the outline of the diaphragm (Fig 2) Lateral films showed the area affected to be entirely in the anterior chest (Fig 3)

The diagnosis was diaphragmatic hernia through the right foramen of Morgagni, containing a loop of large bowel

FIG 4. Barium enema showing the loop of bowel, previously in the chest, now located in the abdomen

The patient was admitted to the Physicians Hospital, Plattsburg, on August 11, 1947 Operation was performed on August 14, 1947 A high upper right rectus incision was made and the coronary ligament divided The opening in the diaphragm was found and the herniated large intestine reduced after adhesions were freed The hernial sac was removed and the rent in the diaphragm closed

Postoperatively, both penicillin and sulfadiazine were given for four days There was no accumulation of fluid in the chest, and the patient was up and about the ward eight days after operation. She was discharged from the hospital five days later

Just before leaving the hospital, x-rays of the chest and barium enemas were taken (Fig 4) These show the colon back in the abdomen and the chest clear A subsequent x-ray of the chest shows an entirely normal chest and heart outline

In January, 1948, the patient reported that she felt perfectly well, had no symptoms, and was employed as a factory worker

Comment

In this instance the symptoms were typically conflicting Gastrointestinal complaints had been present and treated over a long period of time The pulmonary complaints were comparatively recent, but investigation of the cough and expectoration led to the correct diagnosis

The x-rays show the typical increased density

lying in the cardiophrenic angle anteriorly, which is produced by this type of hernia A density so situated is suggestive of the diagnosis If the hernia contains omentum only, the diagnosis will have to rest on this evidence alone until proved by operation The presence of colon in the hernia in this case definitely clinched the diagnosis

All authors agree that this type of hernia should be approached through the abdomen Exposure of the hernial opening is satisfactory, and the freeing of adhesions and reduction of the protruded abdominal viscera can be best accomplished from this direction This procedure must be done with the greatest care and, so far as possible, under direct vision The close proximity of the pleura and pericardium demand meticulous care during the dissection Intratracheal anesthesia should be used so that control of the lungs can be maintained should the pleura be opened either accidentally or intentionally

Either a positive or probable diagnosis of the presence of this condition having been established, operation should immediately be recommended The operation is a safe procedure The meager literature contains far too many diagnoses "proved by necropsy" Pulmonary infection and intestinal obstruction, both imminent dangers in every case, account for the high mortality

Summary

1 A case of diaphragmatic hernia through the foramen of Morgagni showing typical history and x-ray findings is reported

2 Suspected or positive diagnosis of this type of hernia demands the benefit of operative procedure

3 Operation should be performed under intratracheal anesthesia and by an abdominal approach.

SORE FEET

Employes with sore feet cost their bosses $100 million last year This toll of absenteeism and operating inefficiency adds a hefty sum to already swollen business costs Hence, businessmen are scouting around for something to do about their employes' feet The people to whom most businessmen turn for help are the podiatrists (chiropodists)

Recently the National Association of Chiropodists met in Washington, discussed what industry has been doing so far to relieve its workers' tired feet Dr A. Owen Penney, former president, summed up the picture for association members Stores and factories account for most industrial foot ailments There, workers are most apt to throw themselves off balance Corns and bunions, once formed, are aggravated as the workers try to find relief from pain—again, by off-balance stance Dr Penney estimated that 16 per cent of all industrial workers lose as much as a day's work per month because their feet hurt. In addition, aching feet result in slower work, less efficiency in plants In stores, they mean irritable clerks, greater breakage of merchandise, mistakes—even lost sales and angered customers

Store clerks and factory workers are not alone in their suffering Housepainters, roofers, and others who stand for long periods on the rungs of ladders develop a neuralgia of the foot. Delivery truck drivers, because of their habit of jumping from the truck onto the concrete pavement, often develop a painful enlargement of the first ball joint. Then, there is a callous known as "chauffeur's foot" developed by people who spend a great deal of time driving cars or trucks In contrast, there are the many who have foot trouble because their feet get too little of the right exercise

Dr Penney cited Atlanta's Fulton Bag & Cotton Mills as an example of what can be gained through foot clinics Fulton started a free clinic for employes about two years ago Since then, it has reported a drop of 12 per cent in absenteeism, and a rise in production efficiency As a matter of fact, there is a growing list of firms that have taken steps to do something about foot troubles. Woodward & Lothrop, Washington department store, has had a foot-care plan for its employes for twenty-two years The workers go to chiropodists as often as necessary, and the store pays the bill Two other department stores—The Hecht Company, Washington, and Filene's in Boston—have chiropodists come in once a week to check and treat employes' feet The stores pay part of the fee Murray Manufacturing Corporation, in Brooklyn, has a chiropodist visit the plant five times a week When the program was first instituted in 1944, the company paid only a part of the cost. It found, however, that workers failed to utilize the service completely under this arrangement—they were particularly lax about follow-up checks Since 1945, the company has paid the whole cost of the program.

Among large corporations which include foot care in their war-born over-all medical programs are the Henry Kaiser enterprises, Jack & Heintz, Endicott-Johnson, and Sears Roebuck. A survey of working conditions, aimed at preventing foot ailments and accidents, has just been completed in two plants of Ellmore Silver Company, Meriden, Connecticut. Dr Charles Forster, chiropodist who made the study, submitted recommendations, including use of rubber pads on the floor where workers stand all day before machines Many of his suggestions have been put into effect Other companies cooperating in such surveys include Liberty Mutual, Metropolitan Life, Aetna Life, U.S Fidelity & Guaranty, Zurich Insurance, The Mennen Company, Bristol-Myers, and International Shoe

OUR COMMON GOAL THE HEALTH OF THE PUBLIC

JOHN J MASTERSON, M D , Brooklyn, New York

(President, Medical Society of the State of New York)

I AM very grateful for the opportunity of appearing before you today to discuss a subject which is of such growing importance

Health, while always high on the list of topics of general interest, has become in recent years, as you all know, a matter of national concern One has but to read the daily press to become aware that more thought and attention is being given to preserving and enhancing the physical well-being of our citizens than at any other time in our history

There can be no quibbling about the need for taking every step that needs to be taken to achieve this end, and for seeking every means possible to bring it about The medical profession, which I have the honor to represent in the State of New York, holds views in common with all those who feel that good health, for the individual and for the population as a whole, is a heritage that should be denied to no one The Medical Society of the State of New York is dedicated to the service of the people of the State, in order that their constant war against death and disease may not find them without staunch allies and counselors

It seems to me, however, that there has been a tendency of late for the most perplexing problems of ministering to the health needs of our people to get into the hands of persons who are least qualified to handle them There has been a score of suggestions for improving the health services of our nation, some of them in the form of proposed legislation In most cases, there has been a minimum of consultation with the doctors, nurses, public health officers, and other specialists whose advice and experience would enable us to reach a practical and sound solution

One cannot question the sincerity of all who would raise the level of health in this country, but it would be much more realistic if the profession which would be called upon to render the medical service, in the event of the adoption of a national health program, were asked for an evaluation of its practicability

I and my colleagues in the medical profession have a great regard for the splendid work done in New York State and in other parts of the nation by the public health officers and nurses They are, in a sense, the vanguard which holds the line against the ravages of disease and sickness. Without them, the public would be undefended against the unseen enemies which always threaten to strike No one who is familiar with the progress made in the field of public health in recent years can doubt that vast benefits would result from an expansion and intensification of this work

This is recognized by the medical profession, which has advanced a program providing for the interweaving of all the agencies of community life to attain for all the maximum results of health and happiness The general levels of health and added longevity accomplished by health education, medical research and development, and the use of new methods in prevention and treatment of disease, which in this country are beyond compare, should be brought to every doorstep

The American Medical Association has a National Health Program which emphasizes the importance of preventive medicine and public health services It indicates the need for standards of nutrition, housing, clothing, and recreation. Prenatal care, childbirth, infant welfare, and child care are recognized as specialized services in which community effort is helpful Hospitals and health centers are encouraged to meet the needs of communities they serve, and voluntary prepayment plans for hospital and medical care are promoted to finance adequate service Veterans' care of a high standard, supplied to those with service-connected disabilities or in need, is an obligation of good government. Medical research is fundamental to progress The voluntary health agencies have developed uniquely in the United States Health education and fullness of wholesome living round out our health program

By directing our efforts through these channels, the medical profession and the public health workers, functioning as a team, can make still further strides toward the reduction of the incidence of disease, shortening the periods of illness, and lengthening the life of people in all walks of life. This can be done through voluntary effort and without the loss of individual freedom The place for governmental aid is in those areas in which the individual and the community require assistance

A modern health program requires in each locality the participation of leaders from all walks of life Because of their professional experience and training in the field of health and scientific medicine, members of the medical profession should assume leadership With emphasis on prevention, prophylaxis, and the maintenance of vigorous positive health, fewer patients should require hospital care, and the level of health should be improved

The field of health is vast, and there is plenty of room for action for workers of all types, whether their approach be in terms of the population as a whole, or in terms of the individual The important point is for the health officer and the physician to work in a cooperative spirit and blend their efforts to achieve their common goal

In glancing over a volume written by Julian Huxley, called *Man in the Modern World,* I recently came across this passage

> As the barber-surgeon of the Middle Ages has given place to the medical man of today, with his elaborate scientific training, so the essentially amateur politician and administrator of today will have to be replaced by a new type of professional man, with specialized training Life will go on against a background of social science Society will have begun to develop a brain

Presented at the New York Health Conference Lake Placid New York June 21 1949

I think this applies to the point I made earlier regarding the incompetence of some who seek to meddle with problems of national health I also think that it underscores what is going on in the field of public health today More and more the "new type professional man," with his specialized training, is coming to the fore, and under his leadership and guidance the operation of public health departments is reaching new heights

We have such a man in New York State in the person of Commissioner Hilleboe, and I want to take this opportunity to express to him my appreciation, and that of the medical profession, for the fine record he is making in his office He has shown a frankness and open-mindedness which has contributed much to the splendid cooperation that exists between the State Department of Health and the Medical Society of the State of New York With his understanding of the professional point of view and his willingness to discuss all problems, he has brought the physician and the public health worker closer together

They *should* be brought closer together The public health officer is as much a specialist as the pathologist, the radiologist, or the surgeon The public health officer owes the same allegiance to the profession of medicine as does every other type of physician While he owes an allegiance to the State, his first allegiance as a professional man and a servant of the people is to the mother science of medicine, to which we all are indebted He should make it a cardinal principle of his conduct that what is good for medicine as a whole is good for the health and welfare of the public

There have been and there probably will be many more honest differences of opinion between doctors and health officers—there is lots of room for them Most of them undoubtedly arise from the different approach each takes toward problems of health There need be no serious divergence of views, however, no matter what the problem, and there are vast areas where there can be none at all

A very successful pattern of cooperation has been built up by the State Health Department and the State Medical Society, and it has been in existence for many years. Since your last annual meeting, the State Medical Society has suffered a severe loss through the death of Dr Oliver Wendell Holmes Mitchell, chairman of the Committee on Public Health, who did much to initiate many of the programs now in operation His duties now have fallen upon the shoulders of Dr Theodore J Curphey, who is actively engaged in continuing and extending the teamwork of the Health Department and the Medical Society, along the lines followed by the late Dr Mitchell

This cooperation is highlighted by the splendid program of postgraduate medical education, which has helped to keep the level of medical practice so high in this State, with its resulting benefit to the public Other areas in which we have seen productive interchange of views are the establishment of blood banks, preparation for atomic disaster, and the postgraduate training in heart disease, to which the State Society was glad to give its approval We anticipate that the same approach will be followed in handling the cerebral palsy program

Perhaps this cooperation could be extended and made general if local situations were brought before county medical societies more often than they are. Many difficulties which appear to be insurmountable might be overcome if they were discussed on the floor of a meeting of the medical society in the area involved It should be possible to reach a common agreement after a full discussion, with all the elements brought to light and with a desire for teamwork motivating all concerned.

I would like to see more public health officers take an active part in the affairs of their county medical societies There is much to be gained by a mutual approach to common problems

An integrated network of workers in the field of health—public, private, and their assistants—is needed to give to the American people the health services they require. Recently published statements claim that 200,000 Americans die needlessly every year because of inadequate local health departments I do not know how accurate these figures are—we in the medical profession are plagued by flagrantly unreal figures of another kind—but they indicate some need for serious study

You probably are aware of the source of those figures, and the sensational headline used by the national magazine which printed them "The Shame of Our Local Health Departments" It is regrettable that such publicity tends to overshadow all the splendid work that is being done, just at a time when the medical profession is made to appear inadequate to meet the health needs of the nation by the advocates of a national health program

I sometimes wonder, in thinking about the health services which are now available to the rank and file of our population, whether we do not often err in treating good health as a gift which can be easily bestowed upon anyone who wants it There often appears to be too much emphasis upon the *giving* of health, and not enough on the receiving of it By that I mean, the real barriers to good health, in many instances, are not the lack of facilities or the inability to pay doctor bills. The barriers are ignorance and willful neglect, coupled with the failure to observe and practice even the most elementary principles of hygienic living Health must be earned It cannot be given. If there were greater concentration upon the personal responsibility of each citizen to safeguard and promote his own health, there would not be the vast amount of misinformation now current about the inadequacies of either our public health facilities or our medical services.

The hardy American pioneer, who took care of himself and built a sound body to cope with the rigors of his daily life, no doubt would have frowned at being coddled He would have favored the public health workers' efforts to eradicate disease and to promote the welfare of the community But he would never have forgotten his own responsibility to himself—the maintenance of his own health

Much has been done and much remains to be done before we can relax in our efforts and regard the level of health in this country as beyond improvement Present unprecedented health standards are the accomplishment of American medicine and they will continue to progress as long as medicine is kept free to devote itself to the welfare of the community

I subscribe to the remarks recently made in Cincinnati by Dr James R. Miller, a trustee of the American Medical Association, who said

"When a community has a trained health officer with adequate staff, and when physicians succeed in convincing the citizens of the value of a good health program and of their own responsibility for healthy living, there will be established a chain reaction of progress toward better community health which nothing can stop"

NECROLOGY

Moses Akin, M.D, of Ellenville, died on July 11 of a heart attack. Dr Akin, a native of Poland, was sixty-one years old. After graduation from Tufts Medical School in 1925, he served his internship at Beth Israel Hospital, New York. At the time of his death, Dr Akin was a physician and surgeon on the staff of Veterans Memorial Hospital, Ellenville, and was a member of the New York State and Ulster County Medical Societies and the American Medical Association In 1932 he had received a special degree from the University of Vienna.

Patrick J Conroy, M D, seventy-one, a Syracuse physician for the last thirty years, died of a heart ailment on June 11 Dr Conroy received his medical degree from the University of the South Medical Department, Sewanee, in 1901 after taking preparatory work at the University of Buffalo School of Medicine He was a member of the American Medical Association, the New York State and Onondaga County Medical Societies, the Men's Club of St Mary's Hospital, Syracuse, and for ten years was associated with the medical department of the Onondaga County welfare department until his retirement a year ago

Herbert C Fulmer, M D, died on June 16 at Clifton Springs Sanatarium after a short illness He was fifty-eight years old Dr Fulmer was graduated from Syracuse University College of Medicine in 1916 He practiced in Syracuse from 1920 to 1930 and from 1920 to 1948 in Thousand Island Park during the summers From 1934 Dr Fulmer practiced in Daytona Beach, Florida, during the winters

Charles H Haskins, M.D, of Saranac Lake, died recently at the age of fifty-three Dr Haskins, a graduate of Yale University College of Medicine in 1923, was a physician at the General Hospital of Saranac Lake

Ernest Kiss, M D, Queens physician, died on April 14 Fifty-year-old Dr Kiss received his medical degree from the University of Budapest in 1924. At the time of his death he was a member of the New York State and Queens County Medical Societies and the American Medical Association

Jacques Lewinski, M.D, of the Bronx, died on March 5 Dr Lewinski, a graduate of the University of Strassburg in 1912, was formerly a clinical assistant dermatologist in the outpatient department of Bronx Hospital He was also a member of the New York State and Bronx County Medical Societies and the American Medical Association

Francis Joseph McCormick, M D, sixty-two-year-old Ithaca surgeon, died June 30 Dr McCormick had been retired from practice for the last four years because of illness He was graduated from Cornell University Medical College in 1910 and had been a surgeon on the staff of Biggs Memorial Hospital, Ithaca, and consultant surgeon at Willard State Hospital, Willard Dr McCormick was a Fellow of the American College of Surgeons and a member of the New York State and Tompkins County Medical Societies and the American Medical Association

John Conway Russell, M D, eighty-seven, a physician in Saranac Lake for more than fifty years, died on July 10 Dr Russell was a graduate of New York University College of Medicine in 1886

Marie Emilie Ohlmeyer Schroeder, M D, seventy-nine, pioneer woman doctor in Rockland County, died on May 28 after a long illness which had forced her to retire from active practice two years ago Dr Schroeder did postgraduate work in Germany for two years following graduation from New York Medical College and Hospital for Women in 1892 Her first practice was in New York City In 1910 she moved to Nanuet and had practiced there, specializing in obstetrics, until her recent retirement

Heber H Ward, M D, of Brooklyn, died on March 31 at the age of sixty-seven Dr Ward was graduated from the Kentucky University Medical Department in 1905 and had been on the staff of Samaritan Hospital, Brooklyn He was formerly a member of the American Medical Association and the New York State and Kings County Medical Societies

James Franklin Whitwell, M D, practicing physician in Buffalo for fifty-nine years, died June 17 in Deaconess Hospital after a short illness Dr Whitwell, eighty-two years of age, was a graduate of the University of Buffalo School of Medicine in 1890, serving his internship at Buffalo General Hospital the following year He began his association with Deaconess Hospital about 1900 and was for many years a member of the board of directors and of the Hospital's Training School Committee At the time of his death he was a consultant gynecologist on the staff

A member of the Buffalo Academy of Medicine he was honored at a testimonial by that group on the occasion of his fiftieth anniversary as a physician Dr Whitwell had served as president of the Erie County Medical Society in 1913 and was a member of the New York State Medical Society and the American Medical Association as well as the County Society and the Academy of Medicine

MEDICAL NEWS

New York City Lions Club Awards Scholarships to Eye Doctors

FOUR New York University-Bellevue Medical Center physicians were awarded scholarships totaling $2,000 for research in fields related to eye conservation at a luncheon of the Lions Club of New York held June 21 in New York City

Mr Walter Hoving, guest speaker at the luncheon, presented a check for the amount to Dr Daniel B Kirby, professor of ophthalmology, New York University Post-Graduate Medical School, who accepted the gift on behalf of the Medical Center The check represents the fourth annual gift of the Lions Club in aid of the Medical Center's program of postgraduate research devoted to the alleviation and prevention of blindness

Recipients of the scholarships are Dr Arthur Smith, Elmira, Dr James Mayes, Cleveland, Ohio, Dr Irwin Cohen, New York City, and Dr Thomas Heslin, Levittown

Former recipients of the scholarship awards are

1946—Drs Edward Danforth, Charles Goldsmith, Jonathan L Harris, and Hugh McGee

1947—Drs Edward Buckley, George R. Kolodny, Nathaniel Robinson, and Horace Shreck

1948—Drs Goodwin Breinin, Edwin Kent, Walter Mayer, and Charles Toomey

Mr Ernest Fryxell, chairman of the Lions Club Eye Conservation Fund, introduced the scholarship recipients and the guest speaker

Foundation to Merge with American Heart Association

PRELIMINARY steps for merging the American Foundation for High Blood Pressure with the American Heart Association have been approved by boards of both groups, it has been announced by Mr A W Robertson, chairman of the board of the American Heart Association.

The high blood pressure group will thus become a section of the American Heart Association's Scientific Council and will be known as the Council for High Blood Pressure Research Other sections within the Association's Scientific Council now include the Section on Circulation and the American Council on Rheumatic Fever

Under a preliminary agreement approved by the Board of Directors of the American Heart Association and the Board of Trustees of the American Foundation for High Blood Pressure, the staffs of both groups will undertake a joint study to recommend methods of integrating personnel and operations of the two present organizations When such arrangements have been mutually approved, the Foundation will dissolve

Eleven research grants approximating $50,000 for investigation of heart and circulatory disease have been announced by Dr H M Marvin, of New Haven, Connecticut, president of the American Heart Association

The grants include

Long Island College of Medicine, Brooklyn—study of antifibrillatory effect of certain drugs, by Dr Joseph R Di Palma

Albany Medical College, Albany—physiology of atrial and ventricular septal defects and of fixed degrees of chronic valvular stenosis and insufficiency, by Dr Harold C Wiggers

The Research Fellowships are granted for a one-year period, with stipend ranging from $3,000 to $4,000, and are open to graduates of approved medical or graduate schools who are interested in research and intend to follow an academic career

New applications for Research Fellows and Established Investigators will be accepted up to September 15, 1949 Applications may be made to Dr Charles A R Connor, medical director, 1775 Broadway, New York City, 19

To Hold Venereal Disease Seminars

A COMPREHENSIVE series of lectures and demonstrations on the diagnosis, treatment, and management of venereal diseases will start at the New York City Department of Health on Saturday morning, October 8 There will be 12 weekly meetings presided over by experts in the various special fields of venereal disease control Sessions will start at 10 30 A.M and will be held in the second floor auditorium of the Health Department, 125 Worth Street, New York City

The schedule of lectures includes

October 8—The Medical Practitioner and Venereal Disease

October 15—Current Developments in the Treatment of Syphilis

October 22—Antibiotics in Venereal Disease

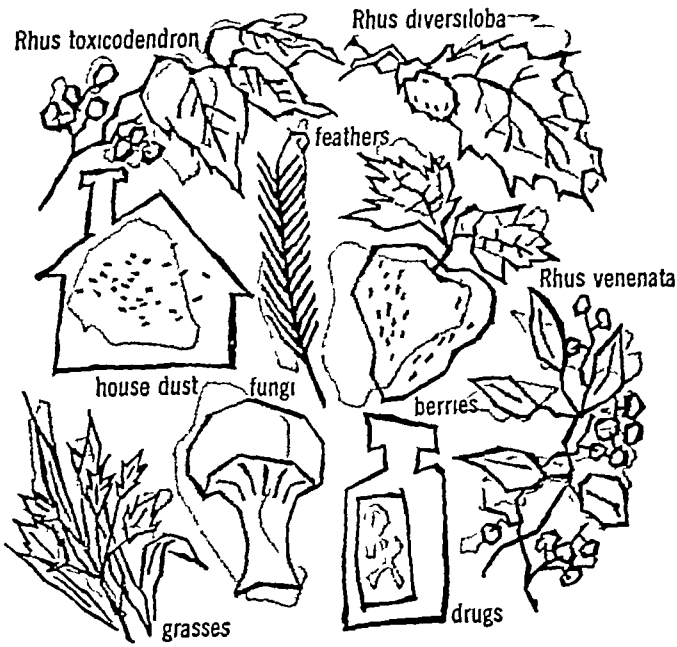
October 29—Clinical Lecture The Chancre of Syphilis—Differentiation from Other Genital Lesions

November 5—Skin Lesions of Syphilis and Their Differential Diagnosis

November 12—Chancroid, Lymphogranuloma Venereum, and Granuloma Inguinale

November 19—Heart Disease and Syphilis in the General Practitioner's Office

November 26—Syphilis of the Central Nervous System



December 2 (Friday, at 1 30 P M)—The Oral Manifestations of Syphilis and the Differential Diagnosis of Interest to Medical and Dental Practitioners

December 3—Serodiagnosis of Syphilis

December 10—The Public Health Nurse's Role in the General Practitioner's Approach to Venereal Disease

December 17—The Syphilitic Pregnant Woman and Her Expectant Child

[Continued on page 1850]

ANTIHISTAMINE THERAPY DEVOID OF DISTRESSING BY-EFFECTS

DIATRIN* A SUPERIOR ANTIHISTAMINIC

HYDROCHLORIDE WARNER'

Allergic manifestations are year-round occurrences, although certain allergic disorders are seasonal in their incidence Changes in diet, readjustments from indoor to outdoor life and spring house cleaning with its attendant raising of house dusts are irritating factors of no inconsiderable importance The arrival of summer brings the rose and grass pollens and the early autumn months are accompanied by heavy weed pollens

In any allergic disorder in which antihistamine therapy is elected Diatrin* Hydrochloride will be found prompt, effective, and safe in action

Diatrin Hydrochloride 'Warner' sugar-coated tablets, 50 mg each, are available in bottles of 100 and 1000*

Announce National Cancer Institute Grants

NATIONAL Cancer Institute grants for cancer training programs, to finance laboratory and clinical research in cancer, and for special cancer control projects have been announced recently, on the basis of recommendations by the National Advisory Cancer Council

Cancer training grants in New York State include

Albany Medical College, Albany, Dr L Whittington Gorham, $24,948, to expand present cancer training program

University of Buffalo School of Medicine, Buffalo, Dr Roswell K Brown, $25,000 to improve present training program

Cornell University Medical College, New York City, Dr Thomas P Almy, $24,975, to continue grant-supported training program

Among the grants of $1,026,294 to finance laboratory and clinical research are the following

Dr Kurt G Stern, Polytechnic Institute of Brooklyn, Brooklyn, $9,936, for studies on desoxypentosenucleic acids and nucleoproteins

Dr Margaret R Murray, College of Physicians and Surgeons, Columbia University, $8,910, for compilation of tissue culture bibliography

Dr Gray H Twombly, College of Physicians and Surgeons, Columbia University, $17,589, for study of selective localization of hormones in normal and cancer-bearing tissues by radioactive estrogens and related substances

Dr Thomas P Almy, Cornell University Medical College, $7,875, for relation of adrenocortical function to leukemia in mice

Dr Paul A Zahl, Haskins Laboratories, New York City, $2,700, effect of gonadotropin suppression on the development of mammary cancer in mice

Dr Konrad Dobriner, Memorial Hospital, New York City, $30,000, steroid hormone research

Dr S M Seidlin, Montefiore Hospital, New York City, $10,000, use of radioactive iodine in study and treatment of carcinoma of thyroid and allied diseases

Dr Harry M Zimmerman, Montefiore Hospital, New York City, $10,000, experimental brain tumors

Dr I Snapper, Mount Sinai Hospital, New York City, $3,000, on the metabolism of 2-hydroxystilbamidine

Dr Anna Goldfelder, New York University, $3,456, investigation of phosphorylated and glycolytic activity of analogous mammary tumors

Drs W C Chambers and M J Kopac, New York University, $22,734, mechanism of cell division and protoplasmic growth

Dr Douglas Marsland, New York University, $2,700, mechanisms of cell division a pressure-temperature study

Dr M J Kopac, New York University, $13,267, ionic exchange during growth, differentiation, and development of marine eggs

Drs Chambers and Grand, New York University, $22,545, etiology of Hodgkin's disease

Dr Arthur L Schade, Overly Biochemical Research Foundation, Inc, New York City, $14,661, studies on growth with the aid of cobalt

Dr W R. Bloor, University of Rochester, Rochester, $10,828, lipid metabolism of tumor-bearing animals

Dr William S McCann, University of Rochester, Rochester, $6,966, metabolic studies on patients with neoplastic diseases

Dr D S Tarbell, University of Rochester, Rochester, $9,828, structure and antimitotic activity of colchicine and podophyllotoxin

Drs Bloor, Hodge, and Stotz, University of Rochester, Rochester, $4,844, relationship of labile methyl groups to the formation of neoplasms in rats on a choline-deficient diet

Dr F C Steward, University of Rochester, Rochester, $11,988, metabolism and nutrition of normal and growing cells

Dr Otto H Muller, Syracuse University College of Medicine, Syracuse, $6,698, polarographic reactions of proteins and polypeptides and their relation to cancer

Special control grants in New York State include

American Cancer Society, New York City, $50,000 for professional teaching films, and $10,000 for lay cancer education films

New York University-Bellevue Medical Center, New York City, Dr William Law Watson, $4,320, tumor registry and follow-up service, and $2,029, tumor examining room-instrument purchases.

Montefiore Hospital, New York City, Dr Daniel Laszlo, $10,000, metabolic studies in human cancer

Teachers College, Columbia University, New York City, Dr R. Louise McManus and Miss Katherine R Nelson, $10,260, survey course of advances in cancer control for clinical instructors and public health nurses

MEDICALLY SPEAKING—

Tropical Disease Diagnostic Service—The Department of Health of New York City has expanded its tropical disease diagnostic service by opening a clinic and laboratory in the Lower East Side Health Center, 341 East 25th Street

This tropical disease clinic and laboratory is the second to be operated by the Department of Health The first, established in 1943, operates in the Washington Heights District Health Center, 600 West 168th Street The new clinic and laboratory will provide consultation, diagnostic, and laboratory services for persons who may have, or suspect they have acquired parasitic infections Private physicians clinics, or hospitals may refer patients to the new clinic for consultation, diagnosis, or treatment, and laboratory specimens may also be submitted for diagnosis Patients at the clinic will be seen by appointment only

Dr Harry Most, associate professor of preventive medicine, New York University College of Medicine and director, postgraduate course in tropical medicine, New York University-Bellevue Medical Center Postgraduate Medical School, is in charge of the new laboratory and clinic He is a member of the subcommittee on tropical medicine of the National Research Council, and of the malaria study section of the United States Public Health

Familiar to every physician are the

patients who need a good tonic

To stimulate appetite, to restore vigor and general tone, Eskay's NEURO PHOSPHATES and Eskay's THERANATES are two of the most useful preparations you have These tonics are prescribed so widely because they work so well

Eskay's Neuro Phosphates

a palatable and effective tonic

Each adult dose, 2 fluid drams (2 teaspoonfuls) contains

Alcohol	10 per cent
Strychnine glycerophosphate, anhydrous	1/64 grain
Sodium glycerophosphate	2 grains
Calcium glycerophosphate	2 grains
Phosphoric acid 75%	1 7 minims

Available in 12 fl oz bottles

Eskay's Theranates

the formula of famous Neuro Phosphates plus Vitamin B1 (0 75 mg. each adult dose) Available in 12 fl. oz. bottles

[Continued from page 1850]

Service, and of many other professional and scientific organizations He has made important contributions to clinical and laboratory research in the field of tropical diseases and was awarded the Legion of Merit in 1946

Research on Blindness in Infants—Mr Charles P Cooper, president of the Presbyterian Hospital, New York City, has announced that the Dunlevy Milbank Foundation, Inc , has established a five-year research program by an initial grant of $46,000 for the first two years, the amount to extend through 1950 It will "inaugurate and carry forward a search for the cause and prevention of blindness in infants, particularly those born prematurely" The grant is to be known as a "Grant for Research in the Cause and Prevention of Retrolental Fibroplasia"

The research on the project will be carried on under the direction of Dr John Dunnington, director of the ophthalmological service at the Institute of Ophthalmology, a unit of the Columbia-Presbyterian Medical Center Dr Algernon B Reese, attending ophthalmologist and pathologist, will be directly in charge of the project

Child Guidance Clinic Teams—Two new child guidance clinic teams, operating in the counties of Suffolk and Nassau, have been set up by the New York State Department of Mental Hygiene, according to an announcement by Dr Frederick MacCurdy, commissioner of mental hygiene The team operating in Suffolk County began work June 1 under the direction of Dr Joseph Haley, formerly supervising psychiatrist at Kings Park State Hospital The Nassau County team, to begin operation September 1, will be under the supervision of Dr Paul G Edgar, who is now senior psychiatrist at Manhattan State Hospital

The department at present has eight traveling child guidance clinic teams, each consisting of a psychiatrist, a psychologist, and a psychiatric social worker During the past year child guidance clinics were conducted in 132 communities throughout the State The clinic teams operating under the department's division of prevention maintain regular schedules in designated cities and towns "During the past year," the Commissioner said, "the Department of Mental Hygiene held over 1,000 child guidance clinics which were visited by more than 7,000 children But even this number falls short of the total need The two new clinic teams, bringing the total to ten, will enable the State to increase its services in this field"

Opportunity for Doctors—There is an urgent requirement for two doctors in the Grand Coulee Dam Area in eastern Washington, population about 7,500 There are now only three general practitioners permanently located in this area General practitioners with special interests in internal medicine, surgery, pediatrics, or obstetrics are needed The United States Bureau of Reclamation has a building in Coulee Dam available for lease to doctors Space totals about 1,200 square feet The Government will spend up to $1,500 toward the cost of remodeling the building into offices as desired by the new tenants Bids from two doctors, or from one doctor willing to rent the space jointly with another doctor, will be opened on September 15, 1949 Housing will be made available

For further details write at once to the District Manager, United States Bureau of Reclamation, Coulee Dam, Washington

To Study Industrial Health at N Y U—Doctors and engineers will join forces to study problems of industrial health, when New York University inaugurates in September a new course in industrial hygiene, offered cooperatively by the College of Engineering and the Institute of Industrial Medicine of the New York University-Bellevue Medical Center The course, planned to meet the growing demand for professional workers trained in the technics of industrial hygiene, is open to physicians and engineers

The new course will begin on September 26, 1949, and will include nine months of didactic teaching and three months of in-plant work. Further information may be obtained from the Dean, New York University Post-Graduate Medical School, 477 First Avenue, New York City 16

Conference of Presidents and Officers of State Medical Associations—Dr Clarence E Northcutt, past president of the Oklahoma State Medical Association, was elected president of the Conference of Presidents and Other Officers of State Medical Associations at the fifth annual session of the group held recently in Atlantic City, New Jersey Dr Julian Price, secretary of the South Carolina *Medical Society, was named as president-elect,* and Mr John E Farrell, executive secretary of the Rhode Island Medical Society, was re-elected secretary-treasurer

Elected as new members of the executive committee were the retiring president, Dr Joseph H. Howard, of Connecticut, Dr Andrew Brunk, of Michigan, and Dr Ross T Wright of Washington

American Board of Obstetrics and Gynecology—The annual meeting of the Board was held in Chicago, Illinois, in May, at which time 236 candidates were certified. New bulletins, incorporating changes made at the recent meeting, are now available for distribution upon application and give details of all new regulations

The next scheduled examination (Part I), written examination and review of case histories, for all candidates will be held in various cities of the United States and Canada on February 3, 1950 Application may be made until November 5, 1949 Application forms and bulletins are sent upon request to American Board of Obstetrics and Gynecology, 1015 Highland Building, Pittsburgh 6, Pennsylvania

Grants for Research in Problems of Nutrition—Research in problems of nutrition in health and disease will be expanded as the result of six new grants-in-aid announced by Dr Robert S Goodhart, scientific director of the National Vitamin Foundation, New York City The grants, made semiannually, are part of a program to discover basic information on the effects and significance of vitamins to human health and resistance to disease The awards, effective July 1, include Dr Leonard J Goldwater and Dr Maurice E Shils, Columbia University School of Public Health, $2,850 to continue work on vitamin deficiencies and the ability of the body to get rid of poisons

Wins Essay Contest—Dr Seymour H Rinzler, adjunct in medicine and cardiology, Beth Israel Hospital, New York City, is the winner of the ninth annual essay contest of the Mississippi Valley Medical Society "for the best unpublished essay on a subject of practical and applicable value to the general practitioner of medicine" Dr Rinzler's paper is entitled "Present Status of

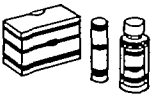
By keeping the incompatibles apart,

YOU CONTROL THE STABILITY

New convenience and flexibility in B complex parenteral therapy Bejectal contains all five major vitamin B complex factors in a sterile solution Chart shows how you can control stability for complete or partial use as needed Bejectal is supplied in 10 cc combination packages through prescription pharmacies

ABBOTT LABORATORIES NORTH CHICAGO, ILLINOIS



SPECIFY

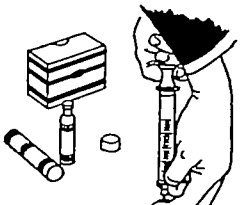
Bejectal®

Abbott s Injectable B Complex Vitamins

AT ROOM TEMPERATURE

STABLE—Indefinitely

UNOPENED

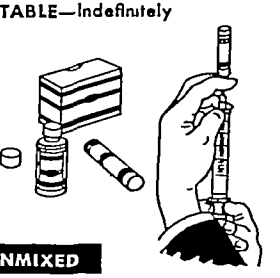


Bejectal remains stable indefinitely When mixed the solution contains:

	Per Vial (10 cc.)
Thiamine Hydrochloride	100 mg
Riboflavin	20 mg
Nicotinamide	750 mg
Pyridoxine Hydrochloride	50 mg
Calcium Pantothenate	50 mg

In Water for Injection U S.P

Benzyl Alcohol 0 9%, is added as a preservative since the mixed solution is for multiple doses.



STABLE—Up to two months

MIXED

This is the best way to prepare Bejectal when you expect to use the entire 10 cc. within 2 months. Simply withdraw 4 cc. of the contents from the small vial with a sterile syringe and transfer to the large vial. Shake and Bejectal is ready for instant use

STABLE—Indefinitely

UNMIXED

When you expect 10 cc. to last longer than 2 months, this is the best way to use Bejectal. For example, whenever you want to inject a 1 cc. dose simply withdraw 0.4 cc. from the small vial and 0 6 cc. from the large vial. Unused portion remains stable until needed

A program may be secured from the secretary, Dr Harold Swanberg, 209-224 W C U Building, Quincy, Illinois

PERSONALITIES

Honored

Dr Horace E Ayers, professor of obstetrics and gynecology, New York Medical College, Flower and Fifth Avenue Hospitals, as guest of honor at the annual faculty dinner at the college Dr G Worden Crissey, Dr Joseph M Purcell, and Dr William Van Doren, all of Mechanicville, whose total years of public service as "family doctors" are 165, at a dinner reception in Troy in May Dr Henry M Selby, New York Hospital, who received a one-year clinical fellowship in radiology from the American Cancer Society Dr Austin J Stillson, family doctor to thousands of Broome County residents for nearly fifty years, guest of honor at a community testimonial and dinner at Ansco Lake on June 29

Appointed

Dr I H Goldberger, assistant professor of pediatrics, New York University Medical School, as director of health education of the New York City Board of Education Dr Philip T Schlesinger, Glens Falls, to the board of directors of the Glens Falls Area Cerebral Palsy Association Dr James L Troupin, New York City, as physician-in-charge of the Ten Mile River Scout Camps of the Greater New York Councils, Boy Scouts of America Dr Theodore J C Von Storch, professor of neurology, Albany Medical College, as chief of the division of neuropsychiatry, Montefiore Hospital, New York City

Elected

As president and secretary, respectively, of the American Psychiatric Association, Dr George S Stevenson, medical director, National Committee for Mental Hygiene, New York City, and Dr Howard W Potter, Brooklyn

Speakers

Dr I D Bobrowitz, Otisville, on "The Significance of Positive Cultures," and Drs Rudolph Berke, Alexander Schomer, and Hyman Bass, New York City, on "Residual Cavities in Pulmonary Coccidioidomycosis Follow-up Studies," at the fifteenth annual meeting of the American College of Chest Physicians June 2 to 5 in Atlantic City, New Jersey Dr Karen Horney, New York City, on "Dynamics of Psychotherapy" at the convention of the American Psychiatric Association May 23 to 27 in Montreal, Canada

Dr John L Norris, Rochester, on "Alcoholics in Industry" at a meeting of the Rochester Advertising Club June 9 Dr John F Rogers, secretary of the Dutchess County Medical Society, on socialized medicine at a meeting of the Dutchess County Women's Republican Club held June 2 in Poughkeepsie Dr Leo F Simpson, Rochester, past-president of the Medical Society of the State of New York, at the joint commencement exercises in Chancellors Hall, Albany, of the Albany Medical College and the Union University School of Nursing, on June 4 Dr J C Zillhardt, Binghamton, president of the Broome County Medical Society, on heart disease at the meeting of the Binghamton Exchange Club May 26 in Binghamton

New Offices

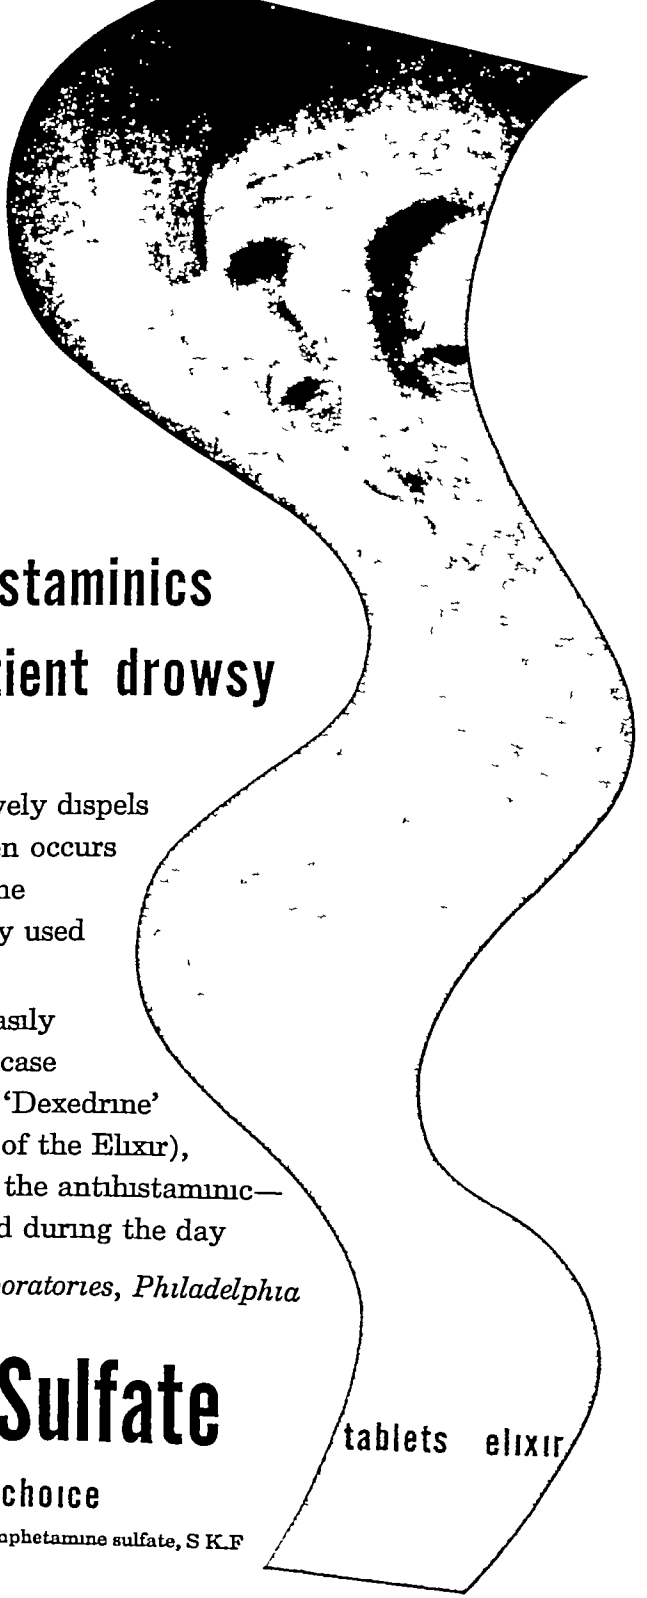
Dr Lyndon R Barnett, who recently received his honorable discharge from the U S Navy Medical Corps, general practice in Roscoe Dr John F Dixon, Jr, formerly of Hempstead, general practice in Dryden Dr William H Kober, Lima, industrial physician with the Pennsylvania Railroad at Harrisburg, Pennsylvania Dr D H R Lester, practice of surgery in Schenectady Dr Joseph Phelps, formerly of Deposit, general practice in Edmeston Dr John C Roemmelt, practice of internal medicine, Elmira

COUNTY NEWS

Albany County

A Cancer Teaching Day, presented by the Albany County Medical Society on May 25, included lectures by Dr Harry Green, Yale Medical College, and Dr H W Dargeon, Memorial Hospital, New York City, on the respective topics "Biological Differentiation of Malignant Tissue" and "Cancer in Childhood" A motion picture illustrating the problems of early diagnosis of cancer was shown by the New York State Department of Health, and Dr George T Pack, Cornell University Medical College, spoke at the evening session on "Diagnosis and Treatment of Sarcomas of the Soft Somatic Tissues"

At the June 22 meeting of the County Medical Society the members voted unanimously to voice their opposition to current legislation, H R. 2893 Also Dr Theodore J C Von Storch of Albany Medical College gave a talk on "Newer Concepts in Neurology"



The second annual joint field day of the Albany County Medical Society and the Albany County Bar Association was held on June 30 at the Shaker Ridge Country Club

Bronx County

Election of officers was held at the annual meeting of the Bronx County Medical Society on June 15, and the following were elected Dr Henry J Barrow, president, Dr Abraham B Tamis, president-elect, Dr Abraham J Fleischer, vice-president, Dr Goodlatte B Gilmore, secretary, and Dr Charles W Frank, treasurer

Speaker at the meeting was Mr William Alan Richardson, editor, *Medical Economics*, who addressed the members on the topic, "Medicine in the British Isles—Spring, 1949"

Now Available

BACITRACIN TROCHES

CSC

- Effective Against Many Oral and Pharyngeal Pathogens
- Low Index of Allergenicity
- Pleasant Tasting

The antibiotic properties of bacitracin can now be advantageously employed in the treatment of many oral and pharyngeal infections due to bacitracin-sensitive organisms Each troche provides 1,000 units of bacitracin, and maintains high bacitracin salivary levels for at least one hour Thus Vincent's infection and other local infections of the mouth, tonsils, and pharynx can be subjected to the direct antibiotic influence of bacitracin

Bacitracin Troches-C S C are outstanding because of their low index of allergenicity Local allergic reactions in the oral and pharyngeal mucous membranes do not complicate their use as with other antibiotic troches Pleasant tasting, each troche remains intact for 1 to 2 hours Available on prescription at all pharmacies in bottles of 25

IT CAN BE DONE
. . . but don't try it!

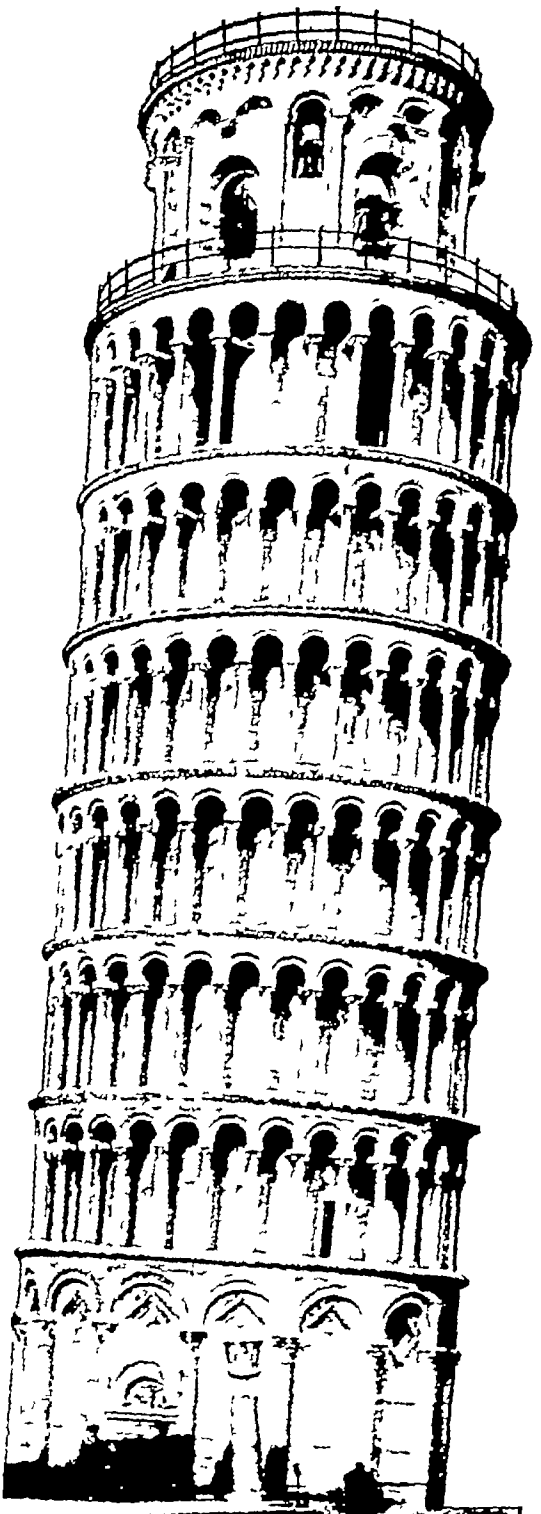
Sometimes it's possible to break all the rules—and get away with it

The famous Tower of Pisa, for instance, has successfully defied both sound engineering practice and the law of gravity for over 800 years

But for most of us, most of the time, the rules hold

That is particularly true when it comes to saving money

The first rule of successful saving is *regularity* saving away part of every pay check, month after month



Once in a blue moon, of course, you'll come across someone who can break that rule and get away with it But the fact is that most of us *cannot*

For most of us, the one and only way to accumulate a decent-size nest egg for the future and for emergencies is through regular, automatic saving

In all history there's never been an easier, surer, more profitable way to save regularly than the U S Savings Bond way

Those of us on a payroll are eligible to use the wonderful Payroll Savings Plan The rest of us can use the equally wonderful Bond-A-Month Plan through our local bank

Use whichever is best for you But—*use one of them!*

AUTOMATIC SAVING IS SURE SAVING— U. S SAVINGS BONDS

HOSPITAL NEWS

Brooklyn, Syracuse Chosen as Medical Centers

THE trustees of the new State University recommended on June 16, by a vote of 10 to 1, that the University locate its metropolitan medical center in Brooklyn and its upstate medical center in Syracuse

The resolution adopted, subject to approval by the Board of Regents, authorizes the executive officers of the State University to enter into and carry out agreements for incorporating into the University the Long Island College of Medicine, Brooklyn, and the Syracuse Medical College, Syracuse University

The State plans to take over the colleges of medicine prior to September and to operate them as integral parts of medical centers at that time

Enrollment per class at the Long Island College is now 110, but the freshman class is expected to be expanded to 150 in September The freshman class at Syracuse, which has been averaging 58 students, will be increased by at least 50 per cent

The 1949 Legislature appropriated $10,000,000 for the State University, and it is expected that more than half of that amount will be spent on the medical centers

The trustees acted upon the recommendation of their Committee on Medical Education, headed by Colonel Charles Garside, which has been studying the problem for nine months

When the State University takes over the colleges, it is expected that most of the faculty members will be retained, with the faculties enlarged

The Medical Education Committee said it restricted its considerations of the metropolitan area center to the Bronx, Brooklyn, and Queens and that the proposals in behalf of the Bronx and Queens envisaged the establishment of a wholly new institution, to which the trustees were opposed.

One of the most compelling factors in support of the Brooklyn proposal, the report added, was "the presence of a well-respected and cooperative faculty at the Long Island College of Medicine The committee has been repeatedly advised that it would take ten years or more to obtain a faculty of equivalent standing if the State were forced to start entirely anew"

At a meeting in July, the Board of Regents approved the selections

Name Medical Board for New Cancer Hospital

APPOINTMENT of the medical board of the Francis Delafield Hospital for Cancer, in Manhattan, which will be affiliated with the Columbia-Presbyterian Medical Center, has been announced by Dr Marcus D Kogel, New York City commissioner of hospitals Approval was given the following nominations received from the trustees of the College of Physicians and Surgeons, Columbia University

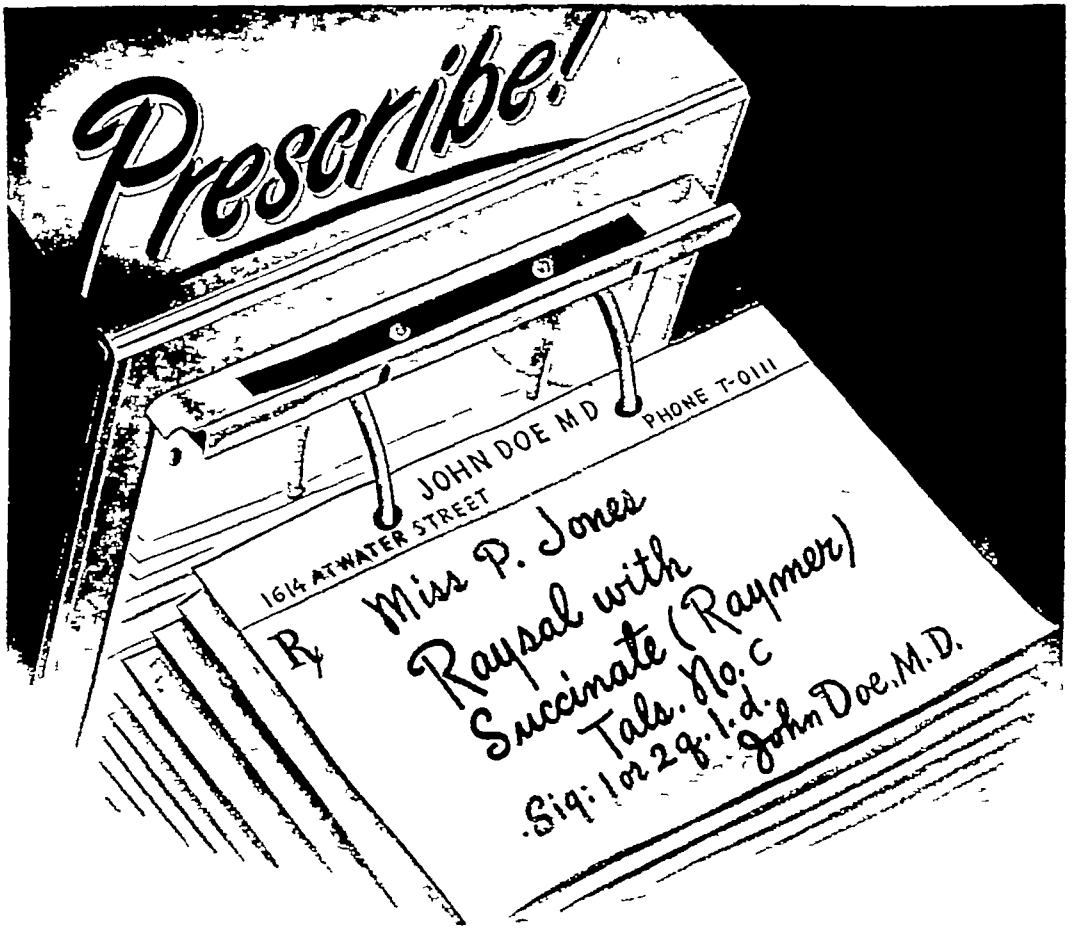
Dr Robert F Loeb, visiting physician and director of medical service, Dr J Lawrence Pool, visiting neurologic surgeon and director of neurologic surgery service, Dr Howard C Taylor, visiting obstetrician and gynecologist and director of obstetric and gynecologic service, Dr Harry P Smith, visiting pathologist and director of pathologic service, Dr Ross Golden, visiting radiologist and director of radiologic service, Dr George H Humphreys, visiting surgeon and director of surgical service, and Dr George F Cahill, visiting urologist and director of urologic service

Dr Willard C Rappleye, dean of the College of Physicians and Surgeons and vice-president in charge of medical affairs, Columbia University, will be ex officio member of the new medical board.

Dr Kogel stated in the general order making the appointments that "the individuals above named are hereby declared to be the medical board of the Francis Delafield Hospital, and the medical board is authorized to proceed in due course with the organization of a complete medical staff, subject to the rules and regulations of the Department of Hospitals"

Cornerstone ceremonies for the hospital were held in September, 1948, and it is expected that the 308-bed hospital will be in operation early in 1950

Award Contracts for New Building at Binghamton State Hospital



CONTRACTS totaling $6,468,562 have been awarded for construction of a 768-bed Medical-Surgical Building at Binghamton State Hospital This important addition to Binghamton State Hospital is a part of New York State's $72,000,000 building program to relieve overcrowding in its 27 mental institutions, urged by Governor Thomas E Dewey as one of the State's most pressing needs

Construction is to start this summer and will require two to three years for completion The new building will be located northeast of the existing Fairmont Building, and will have the most modern laboratory and hospital equipment to provide the best medical and surgical treatment for physical illnesses and disabilities of mental patients who regularly receive this care in addition to therapeutic psychiatric treatment for mental disorders

Binghamton State Hospital is virtually a small city in itself with its own power plant, fire-prevention system, farms, shops, and nurses' homes. The present hospital houses more than 2,600 patients and provides supervision for an additional 230, while about 60 have been placed in family care homes in the vicinity

The new building project is one of several planned by New York State to relieve overcrowding in its 27 mental institutions, which are now caring for more than 99,000 patients It is the third large medical-surgical unit to be advanced for construction this year, being similar to those already under construction at State mental hospitals at Poughkeepsie and Buffalo

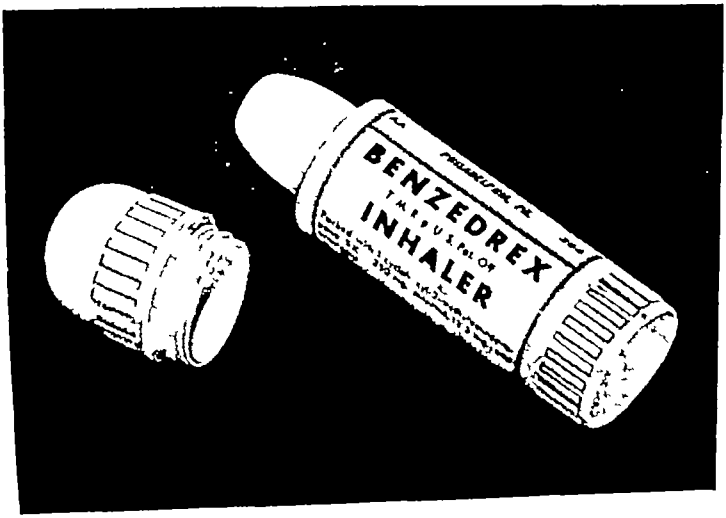
Announcing the new S.K.F. Inhaler!

BENZEDREX INHALER

So much better that



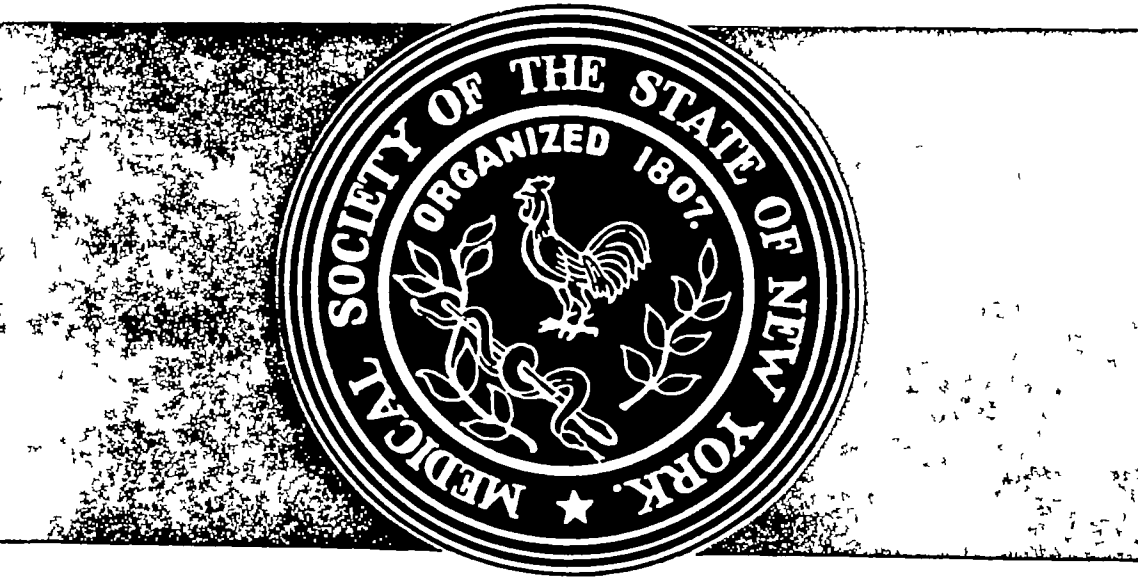
we have discontinued 'Benzedrine' Inhaler

'BENZEDREX' INHALER is such a major improvement that we are actually withdrawing 'Benzedrine' Inhaler from the market

The active ingredient of BENZEDREX INHALER is 1-cyclohexyl-2-methylaminopropane, a new S K F compound It has exactly the same agreeable odor as Benzedrine*, gives even more effective and prolonged shrinkage, and does NOT produce excitation or wakefulness

We are sure you will find that BENZEDREX INHALER is the best volatile vasoconstrictor you have ever used

Smith, Kline & French Laboratories, Philadelphia



*'Benzedrine (racemic amphetamine, S K F) and 'Benzedrex' T.M Reg U S Pat Off

Each BENZEDREX INHALER is packed with 1-cyclohexyl 2 methylaminopropane, S.K F, 250 mg, and aromatics

THE CLIFTON SPRINGS SANITARIUM AND CLINIC

CLIFTON SPRINGS, NEW YORK

Hospital and Clinic Building

Sanitarium Main Building

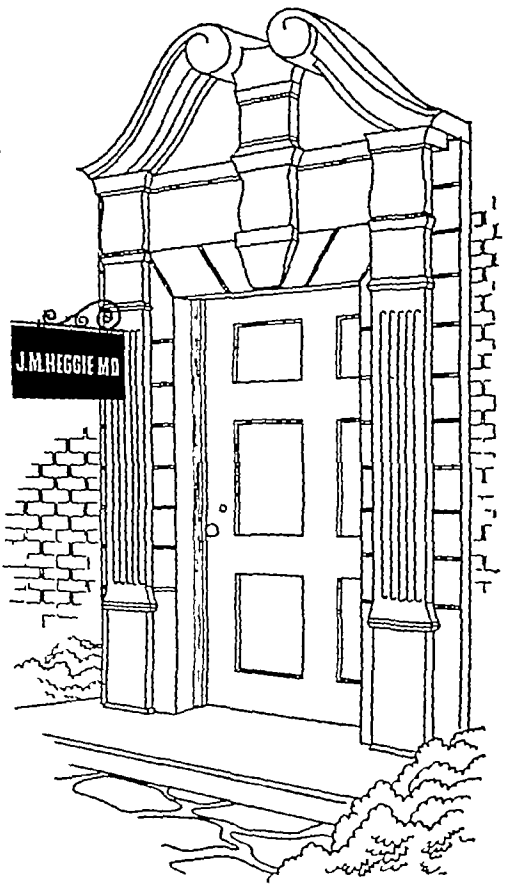
THE CLINIC

Medical sections for the care of metabolic and cardiovascular diseases, arthritic, psychoneuroses, gastroenterology, pediatrics and hematology, as well as general diagnosis are available Surgical sections are available for general surgery and the various surgical specialties Laboratory sections are maintained for radiology and pathology

The clinic is general and maintains competent medical, surgical and laboratory staffs All types of general medical and surgical cases are received for diagnosis and treatment Recognized forms of physiotherapy are provided There is an excellent dietetic service No cases of active pulmonary tuberculosis, contagious disease, epilepsy, or insanity are accepted

THE SANITARIUM

REST, RELAXATION, MEDICAL CARE



The Sanitarium has all the atmosphere of a fine hotel with individual rooms and tasteful decorations A special feature is made of occupational therapy of all kinds with competent staff and facilities Other features are large cheerful solarium, billiard room, complete gymnasium, complete bath and massage department The spacious grounds include a nine-hole golf course All the sanitarium facilities are open to guests who do not wish examination and medical care, but come simply for the baths and massages and rest and recreation Modern medical equipment and superb location offer the combined advantages of a medical center and rural Spa

49 SEPTEMBER 1, 1949 NUMBER 17, PART II

Minutes of the House of Delegates, 1949

s year the Publication Committ- sc to the wishes of the mem- esents the minutes of the House c in a single volume, Part II, of f the JOURNAL

riment, undertaken in 1948, c so successful that doubtless this ll continue indefinitely with per- modifications from year to year the convenience to the member- ing the House of Delegates min- volume with its own index, it to obtain earlier publication of e transactions than was formerly they were published serially in A

noted that this year original appear in full but once To avoid l expensive) repetition, subse- ences to the original omit the "whereases," but the reader will have no difficulty in locating the original in the event that he desires to do so The editing of verbatim minutes presents complicated problems which the Publication Committee has attempted to solve by condensing and eliminating nonpertinent matter in so far as this can be done without altering the meaning

Part II is widely read, it is retained for reference purposes, the reporting of discussion from the floor of the House in full is appreciated, and because of its compact character it is retained by members and is frequently consulted In its one-volume form it requires little library shelf space, and the issues as they appear from year to year will provide a readily accessible, convenient record of the transactions of the House of Delegates of the Medical Society of the State of New York

with medical thought in other states and in the American Medical Association

Uninformed persons, antagonistic to the American Medical Association of which we are a part, of whom fortunately few are in the medical profession, try to cause dissension in our ranks by declaring that what they speak of in a derogatory way as "organized medicine" is run by a group of dictators who attempt to control the thoughts and actions of the medical profession We know that this is not so You, the delegates to our House, represent in a real way the grass roots of our profession You have been chosen by your respective county medical societies as representing the best interests of the profession, and many of you have been instructed by your component societies as to the stand you are to take on important matters coming before the House, and a part of your duty will be to elect officers and councilors who will carry out the policies you decide upon and to report back to you every detail of the work they have done You will also elect, very largely from your own members, delegates to the House of Delegates of the American Medical Association, who will represent this State. Where is there a more democratic form of government?

The number of resolutions annually made at this session and the number of reports of activities of the officers and Council and the various committees have made it necessary to split the membership of the House into twenty-one reference committees The work of these committees is most important It is essential that not only the members of the House and the members of the Council and committees interested in, and having special knowledge of, any subjects coming before these reference committees should attend their deliberations, but that anyone who wishes to express opinions on the question at issue should also be given a hearing The reference committees can then, if they think it wise, make changes in resolutions and make definite recommendations to the House, thus saving much valuable time We should not spend too much time in arguments at our full sessions

In order to aid the Speaker this year in making his appointments to the reference committees, the secretaries of your county medical societies were asked to send in certain information regarding your type of practice, your hospital and teaching affiliations, and the character of the work you had done in your respective societies Although many of these reports unfortunately arrived too late to be of use in this connection, there was sufficient information at hand to enable him in most cases to select members who know about and enjoy the consideration of the type of resolutions which their reference committees will be called upon to consider I am sure you will nearly all be happier in your assignments this year

It will interest you to learn that, of the 154 elected delegates, including a few alternates, about whom we finally obtained the information we asked for, all but five, who are administrators or officers in the government services, are actively engaged in the practice of medicine, all are connected with hospitals Thirty-four, or 22 per cent, are general practitioners, 38, or 25 per cent, are surgeons, 25, or 16 per cent, are internists, 13, or 9 per cent, are obstetricians and gynecologists, and 44, or 28 per cent, are specialists in 13 different qualifications or categories, including nine otolaryngologists, eight urologists, four gastroenterologists, three roentgenologists, three neuropsychiatrists, and two each of anesthesiologists, bronchoscopists, dermatologists pathologists, and ophthalmologists, seven other specialties are represented by one delegate apiece All of you are, or have been, officers and members of important committees of your county societies Eighty-one of you, or 53 per cent, have been presidents Twenty-five, or 16 per cent, hold important teaching positions in medical schools The high percentage of general practitioners refutes the contention that the opinions of our medical societies are entirely controlled by specialists It would be expected that specialists, who have more time to give to organization matters, would be in the majority, but, after all, specialists depend largely upon general practitioners for their livelihood and are certainly interested in their welfare

It is with great regret that your Speaker announces the death during the past year of three of our most valuable members, as follows

Dr Albert A. Gartner, of Buffalo, chairman of the Board of Trustees and long a hard worker for our Society

Dr O W H Mitchell, of Syracuse, a Councilor for many years and chairman of our busiest committee, that on Public Health and Medical Education.

Dr Leo S Schwartz, long a delegate from Kings County, and an active worker for the good of the medical profession

The House is requested to rise for a period of silence in honor of these departed members

The delegates arose and observed a minute in silent memory of these departed colleagues

SPEAKER ANDRESEN The Chair will entertain a motion to have the Secretary send suitable letters of sympathy to the families of these deceased members

DR. EDWIN A. GRIFFIN, *Kings* I so move.

DR. LEO F SCHIFF, *Clinton* I second the motion.

There being no discussion, the motion was put to a vote, and was unanimously carried

SPEAKER ANDRESEN It is so ordered. That will be done

SECRETARY ANDERTON Yes

SPEAKER ANDRESEN I would now like to ask the new members of the House to arise, so that we can see who you are.

Over fifty arose

SPEAKER ANDRESEN There are too many of you to ask each of you to give your name at this time, but I hope you will all take an active interest in what is going on and take part in the discussions

For many years it was a custom to introduce the member of the House who had seen the longest service in the House Last year, with the passing of Dr Robert Brittain the previous winter, after fifty-five years of such service, we did not have any information regarding our oldest member in point of service, but after a year's research we have found two members who were first elected delegates in 1913, and who have attended our sessions regularly ever since—a record of continuous service for thirty-six years Both come from a city in which the principal recreation for the young people is to listen to the meetings of the State Legislature and, as would be expected, both are expert parliamentarians and have contributed very greatly to the proper conduct of our meetings It gives me great pleasure to introduce to you our two eminent members, Drs Arthur J Bedell and James F Rooney I am sure we would appreciate hearing a few words from each of these men (*Applause*)

There was no response

SPEAKER ANDRESEN Well, we will ask them to speak a few words to us when they do come in.

SPEAKER ANDRESEN If any chairmen find that members of their committees are not present, and will let us know, we will appoint other members to fill out their quota

The reference committees are going to meet in the Ballroom Foyer, is that right?

SECRETARY ANDERTON Yes

SPEAKER ANDRESEN The stenographers to type the reports will also be located there

Anybody who wants to make a resolution must have nine copies made of it, so that these can be distributed to the five members of the reference committee and also to the proper authorities in the secretarial department

I want to emphasize that those who are interested in any subject that is referred to a reference committee should appear before those reference committees this afternoon for discussion so as to avoid too much time being spent in discussion on the floor of the House that could just as well have taken place in the reference committees today

Section 4

Announcements

The Speaker announced the Annual Banquet would be held at 7 P M Wednesday He also drew attention to the exposition of matters dealing with the National Educational Campaign of the American Medical Association in the press room on the mezzanine floor

Section 5 *(See 17)*

REMARKS OF THE SPEAKER

SPEAKER ANDRESEN Members of the House of Delegates, it is with the greatest of pleasure that I greet you as your Speaker once more This is going to be one of the most important meetings our House of Delegates has held. Questions of great moment not only to the medical profession and the public health but of vital importance to the public at large will come before you, and your action will be watched with interest all over the country We must realize that the decisions of this body have great weight

Section 9 (See 121)

Supplementary Report of the Malpractice Insurance and Defense Board

To the House of Delegates, Gentlemen

This supplementary report covers investigations made by this Board into the matter of malpractice claim prevention It is based principally on a close study of the Alameda County (California) Medical Association's program as well as a similar but older plan in Los Angeles County, together with information obtained through a personal interview with Dr Hurff, chairman of the Malpractice Defense Committee of the New Jersey State Medical Society, and correspondence with the secretary of the Connecticut State Medical Society

Alameda County Medical Association The claim prevention plan of Alameda County is only a part of a bold, progressive venture into a wide field of public relations and medical economics which has as its purpose a cure for most of the ills which afflict the profession in these two general fields All activities are woven together in an integrated program, and for that reason claim prevention is somewhat dependent upon other departments, such as the Bureau of Medical Economics which undertakes to arbitrate economic differences between doctors and patients, the Medical Social Service which investigates home conditions, medical services required, and ability to pay, and the collection service which is self-supporting and which handles collections of members' bills in a manner calculated to prevent counter-claims for malpractice This service frequently discovers and reports dissatisfied patients with grievances which, if not caught in time, might develop into suits

Reduced to its simplest terms, the claim prevention program can be described as based upon the theory that an injured patient is entitled, without cost to him, to whatever corrective procedures are necessary to repair the damage, whether the doctor was right or wrong, and that he is entitled to reasonable reimbursement for loss of time and for pain and suffering if, in the considered judgment of the medical experts, the doctor was at fault If the doctor was not at fault, any payment beyond the cost of the corrective treatments is resisted solidly by the entire county organization This theory can easily be stated, but to put it into practical application requires a great deal of organization, hard work, discipline, and close cooperation between the county organization, the members, their legal service, and their insurance company

Every member is required to report to the county association immediately any occurrence or condition which he observes in his own patients or those who come to him from another doctor, which he thinks may lead to a dissatisfied patient and a malpractice claim. From there on, no set procedure is followed, because no two cases are alike But, generally speaking, the case is reported to the insurance company, whose claim representative enters the case and thereafter takes part in all considerations of it The patient is fully informed as to his condition, an examination is made by the best expert available, corrective procedure is decided upon, and carried out when not refused by the patient The ablest man available in that part of the state is brought in, if necessary, for consultation or for the corrective procedure, all of which is paid for by the insurance company and charged to the loss experience of the group

All the doctors involved are brought together for a frank, friendly, and helpful discussion of the case The doctor s and hospital records are examined, and finally a determination is made as to whether or not the doctor was at fault Throughout this period there is no criticism of anyone. All members are presumed to have a common interest in the case, and those involved put their shoulders to the wheel and push together

When the patient has recovered or has been restored to the best physical condition possible in the circumstances, the question of a monetary settlement is taken up if the doctor has been judged at fault

Compliance with the requirements of this program is undoubtedly voluntary on the part of a large majority of members, as no doubt it would be among conscientious doctors anywhere. But there are enough members who do not willingly subscribe to the program so that it could not have been brought to its present effectiveness in the absence of sanctions or penalties which may be applied to secure discipline and compliance There are various penalties provided, and they are applied with great care to fit each individual case While the weight of medical opinion in a neighborhood is, in itself, a potent corrective factor, the following specific penalties may be used when required

(*a*) *In Hospitals* A member may be denied the right to undertake certain treatments or procedures in his hospital or required to undertake them only in the presence of a member of an appropriate American college or board of specialists In some cases, hospital privileges may be withdrawn entirely

(*b*) *Insurance* A member's insurance may be endorsed so as to exclude protection on account of certain treatments or procedures It may be reduced to a minimum of $5,000 It may be endorsed so as to require the member to bear the first $500 or $1,000 of any loss caused by him, or his insurance may be cancelled outright

(*c*) *County Association* Under procedure laid down by the State Association, a doctor may be expelled from membership in the County Association

The whole purpose of the plan is to get to the injured patient as quickly as possible and to do whatever is necessary to repair the damage as completely as possible and thus prevent potential claims from developing into suits To accomplish this requires the fullest cooperation by all members, who accept the principle that a malpractice suit against one member is the concern of all of them

Many cases were cited to show the number of malpractice suits which have been avoided and the money which has been saved On the showing of these cases alone, there can be no doubt that the plan works It reduces the number of malpractice suits and the cost of disposing of malpractice claims It has eliminated or minimized many abuses which give rise to malpractice actions, and thus it has improved the quality of medical service in the county and increased the respect and confidence of the public

The Alameda County program has been developed under the inspiration and effective leadership of Mr Roland Waterson, the executive secretary, staunchly supported by the leading members of the Association Mr Waterson is careful to point out that it has taken at least four years to develop their program, which is not yet considered complete As each county activity is organized and put in working order, an assistant is put in charge of it, thus freeing Mr Waterson s time to go on and develop other services

The insurance plan of the Association is frankly an experiment which has not yet proved itself It is

Section 6

Reference of Reports and Supplementary Reports

SPEAKER ANDRESEN The Secretary wishes to announce that the reports and supplementary reports of Officers, Council, etc, have been distributed Will you announce that?

SECRETARY ANDERTON The reports and supplementary reports of Officers, Council, Trustees, Legal Counsel, and District Branches that have been published and distributed to the members of the House have been referred to the respective reference committees. I move, sir, that the reading of these reports be omitted

DR. CLARENCE G BANDLER, *New York* I second the motion

There being no discussion, the motion was put to a vote, and was unanimously carried

SPEAKER ANDRESEN They have been referred directly to the reference committees, and will be considered tomorrow

The following supplementary reports were mailed to each member of the House of Delegates under date of April 25, 1949

Section 7 (*See 125, 169*)

Supplementary Report of the Secretary

To the House of Delegates, Gentlemen

On March 14, 1949, the Council elected Dr Theodore J Curphey of Hempstead, Long Island, to succeed the late Dr O W H Mitchell as chairman of the Committee on Public Health and Education Dr Curphey has been our Second Vice-President during the past Society year He has already efficiently commenced his important duties

In accordance with plans formulated by the late Dr Mitchell, in cooperation with the New York State Department of Health, President Leo F Simpson, with the approval of the Council, in February appointed the following Regional Chairmen for Internal Medicine to function under the Public Health and Education Committee

Region 1	New York Richmond, Bronx Dr Scott Johnson New York City
Region 2	Kings Queens, Nassau Suffolk Dr Alfred P Ingegno Brooklyn
Region 3	Westchester Rockland Dutchess Putnam Orange Dr Scott Lord Smith, Poughkeepsie
Region 4	Schenectady Fulton Montgomery Schoharie Greene Ulster Dr Frederic W Holcomb Kingston
Region 5	Albany Washington Saratoga, Columbia Warren Rensselaer Dr L. Whittington Gorham, Albany
Region 6	Clinton Essex, Franklin St Lawrence Dr Daisy H. Van Dyke Malone
Region 7	Jefferson, Lewis Herkimer Hamilton Dr John M Rice Watertown
Region 8	Onondaga Oswego Oneida Madison, Cortland Cayuga Dr Charles D Post, Syracuse
Region 9	Broome Tioga Chenango Otsego Delaware Sullivan Dr Clifton H Berlinghof Binghamton
Region 10	Monroe, Orleans Wayne, Livingston Ontario, Yates Seneca Dr Benedict J Duffy Rochester
Region 11	Chemung Schuyler Steuben Tompkins Allegany Dr F S Hassett, Elmira
Region 12	Erie, Niagara Chautauqua, Cattaraugus Genesee Wyoming Dr Roy L Scott Buffalo

These chairmen have already demonstrated their helpfulness by constructive comments on the cardiac teaching program proposed by the New York State Department of Health, Dr Herman E Hilleboe, commissioner, and Dr I Jay Brightman, assistant director, Division of Medical Services

Your Secretary spent Lincoln's Birthday at the American Medical Association in Chicago with Dr Floyd S Winslow, Dr George W Kosmak, Mr. Dwight Anderson, Mr Frederick W Miebach, and Mr Thomas E Walsh, representing the Society at a meeting where the campaign to enlighten the citizens of our country regarding the practice of medicine and its accomplishments was discussed.

As a result of notices sent from your office, 7,747 of our 22,505 members had paid their American Medical Association assessment by April 5, 1949

Respectfully submitted,

W P ANDERTON, M D, *Secretary*

Section 8 (*See 124, 133, 139*)

Supplementary Report of the Board of Trustees

To the House of Delegates, Gentlemen

Frequent conferences and thoughtful consideration of the financial affairs of the Society prompts this supplementary report of the Board of Trustees

We call attention to the fact that the net cost of publishing the *Directory* this year is $88,000 The Board of Trustees recommends that the *Directory* hereafter be published once every four years instead of every two, and at the intervening two-year period that a supplement without advertising be published listing the names of physicians who have come into practice since the *Directory* was last issued To this end, it will be necessary to rescind the decision by the House of Delegates to publish the *Directory* once in two years

Careful financial study by the Trustees and due consideration of the experience of the Publication Committee prompts the Board of Trustees to recommend that the listing of physicians in Connecticut and New Jersey be eliminated from future publications of the *Directory* because of the expense involved

Further thoughtful study of the resources of the Society might tend to diminish or modify hasty financial references to the Board of Trustees The Society carries on large activities It is increasingly difficult for each department to realize what another department desires to spend. The Board of Trustees asks the Council to exercise due caution in requesting the spending of the Society's money on new or uncertain impulses In this period of social evolution in which medicine has come to have increased responsibility, it is highly necessary that finances be kept in a sound condition and proper reserves maintained, and that the principles of the function and obligation of the Board of Trustees as laid down in the Board's report this year be kept in mind

The Trustees freely state that it is an easy thing to spend the other fellow's money When it is decided to spend money, we should pause long enough to take a thoughtful look into the future and consider what is for the best interests of the Society and what may be involved in meeting the problems confronting the profession of medicine in the present distraught, puzzled, confused, and uncertain world

Respectfully submitted,

WILLIAM H ROSS, M D, *Chairman*
JAMES F ROONEY, M D
EDWARD T WENTWORTH M D
EDWARD R CUNNIFFE, M D
DAN MELLEN, M D

larger number of members and a wider diversity of interests However, the same sanctions and penalties are used in both counties and in Los Angeles these are more responsible for the cooperation obtained than in Alameda County The use of the deductible average clause up to $1,000 has proved very effective in Los Angeles Only one member with a deductible clause attached to his insurance has been sued the second time, whereas, before the adoption of this penalty, more than one suit against the same doctor was not uncommon The extent to which the members approve this penalty is illustrated by the fact that some years ago a $250 deductible clause was attached to the insurance of all plastic surgeons Recently, when the Association offered to eliminate this provision from their insurance, the plastic surgeons held a meeting and unanimously voted to have it retained.

Little or no information could be obtained about the details of the insurance plan There is no agreement between the company and the Association as to what percentage of the premiums is allocated to losses and operating expenses and the Association has no knowledge of the actuarial details of the plan or how it is rated All of the operation and much of the claim work is left to the company, which has the right to cancel individual policies for cause, and this right is exercised freely Dr Regan, the executive secretary of the Association, agreed to get from the insurance company a schedule of their rates and other information bearing upon this insurance plan and send it to the Board, but this had not been received up to the time this report was prepared. He did state that about $15,000 a year is paid by the insurance company to the Association to defray the cost of their claim-prevention program.

Although no information was obtained as to the loss ratio up to date, a review of the many cases which were prevented from developing into suits indicates that the loss experience, whatever it may be, would have been much higher had it not been for their effective claim-prevention plan

Dr Regan, in addition to having practiced medicine successfully, is an attorney admitted to practice in California. He has spent some years in the study of the legal liability of the medical profession and how to avoid as well as how to defend malpractice claims It may be assumed, therefore, that most, if not all, of the claim-prevention program of Los Angeles County was developed by him and has grown under his leadership Dr Regan stated that he visits and talks with the staff of every hospital and meets with every organized specialist group in Los Angeles County at least three times a year

It has been said that the medical men of California have been driven by a combination of many factors to band closely together in self-defense However true that may be, contact with the activities of these two county medical associations creates the impression of fresh and vigorous ability to devise new solutions for old problems and, by hard, cohesive efforts, to make them work

Dr Regan and Mr Waterson gave a great deal of their time to a thorough explanation of their situations and programs, and the Board desires to record its appreciation of their helpful cooperation

Connecticut Each of the component county medical associations of the Connecticut State Medical Society has a Committee on Medical Ethics and Department, whose sole purpose is to review and comment upon threatened and actual suits of professional malpractice

All cases of this nature are referred to these county committees and, when necessary, the Committee confers with the legal counsel of the company which carries their group professional liability insurance. It is felt that as a result of this procedure the number of suits for professional malpractice in Connecticut has dropped considerably

No concrete figures have been obtained from this source Although it is known that the premium rate in Connecticut is lower than it is in New York State, it is also well known that the average verdict rendered by Connecticut juries is considerably less than those rendered in New York State This investigation will be continued at some convenient later date

New Jersey The modus operandi in New Jersey is essentially the same as in Connecticut The larger component county societies have special standing committees to investigate malpractice claims Similar service is rendered the smaller counties by special advisors appointed by the State Medical Society The plans of both of these states differ from our own in that the state society does not have all the actuarial data necessary for adequate determination of premium rates and lacks any control in the setting of these rates

Conclusions As a result of its investigations, this Board concludes that the number and cost of malpractice suits against our members can be reduced by a claim-prevention program carefully designed to fit the situation of our counties or groups of counties, provided that it has the strong support of a majority of the members of the various component groups The program should include such activities as education of individual practitioners in how to avoid such claims and investigation into claims when made, with an endeavor to secure the cooperation of all physicians concerned Such a plan would be a radical departure from our established procedure and should be organized with the greatest care.

This Board has received from the Council authority to establish "pilot" committees for this purpose in certain selected test counties It would not be advisable to attempt to inaugurate this plan on a State-wide basis at one fell swoop The organization of these pilot committees should be carried out with the greatest care, and their operation closely observed in cooperation with this Board and the Counsel of the State Society As the pilot committees establish their value, other committees could be organized in other counties or districts as the case might require, with the idea of eventually covering the entire State

The results of such a program should not be expected to produce a decrease of insurance rates for a considerable period, perhaps four or five years, because acts which form the basis for the claims or suits that will arise during those years have already been committed Aside from monetary considerations, however, any program which can reduce the incidence of preventable claims is a service, not only to the members of the Medical Society, but also to the good name of the medical profession as a whole, and to the public whose welfare depends upon close adherence to the high standards of ethical practice by all members of the medical profession.

Respectfully submitted,

LEO F SCHIFF, M D , *Chairman*
CHAS GORDON HEYD, M D

CHRISTOPHER WOOD, M D
THOMAS M D'ANGELO, M D

written for a five-year term, at the end of which a new contract will be negotiated. It does not appear to be based upon normal actuarial computations It provides for rate changes from year to year which appear to be more in the nature of rewards or penalties for yearly results rather than adjustments upon actual costs which cannot be determined until five or six years have elapsed Furthermore, it does not appear that any reserves are established for the incurred but not reported cases This is the factor which has made malpractice insurance rating difficult for all companies, so unless such reserves are provided for in some manner not shown in the carrying agreement, the end results at some time in the future may be quite different from those now contemplated by the Association and the insurance company

Under the plan only 50 per cent of the premiums are available for losses and loss expense Annual premium dividends amounting to 20 per cent, which normally would be credited to the individual members, are paid to the Association and used to defray the expense of producing and supervising the business, keeping records, etc This leaves 30 per cent available to the company for their profit and operating expenses which do not include any acquisition cost (commissions) This appears very attractive from the company's standpoint because their published expense ratio, including commissions and agents' salaries, averages only about 16 per cent Nevertheless, the insurance plan, up to date at least, has served the needs of the members admirably, at rates approximately half those charged by Lloyd's of London, which is the only other organization writing malpractice insurance in that part of the state In addition, the enthusiastic assistance and cooperation of Mr Thomas Hadfield, the resident vice-president and manager of the company, has been of very great value to the Association

Last year, it was reported that the plan had paid out only $750 in three years and it was this figure which first attracted the favorable notice of the Medical Society of the State of New York. Figures recently obtained from the Association show that, near the end of the fourth year, $4,300 has been paid out in closed claims and reserves of $23,000 have been established for seven suits which have not yet been tried. Because of the unusual delay in the development of malpractice actions, four years is too short a period upon which to predicate conclusions as to what the ultimate loss experience may be Also, the apparent failure to provide reserves for incurred but not reported cases increases the possibility that the final loss experience may be disappointing However, consideration of the actuarial aspects of the insurance plan should not be permitted to detract from the excellent results achieved by the claim-prevention program. Without it, the loss experience up to date would undoubtedly have been very much higher and the members would probably be paying twice as much for their insurance.

Los Angeles County Medical Association The claim prevention program in Los Angeles County was inquired into by the Board because it is older than that of Alameda County and is credited with having inspired much of the plan adopted by the latter Association It is also of interest to the members of the Medical Society of the State of New York because the 4,600 members of Los Angeles County serve a population comparable in size with the largest counties in metropolitan New York.

The Los Angeles County Association has not developed a public relations or medical economics pro-

nized and efficiently carried out The basic principles are the same as those described above Immediate action and unlimited care and funds for corrective measures to rehabilitate injured patients are first considerations in every case In one case cited, a neurosurgeon was flown to Los Angeles from Washington, D C , to repair the nerves and tendons of a boy's hand, which had been severed in two places Complete function and use of the hand was restored The cost of the repairs was probably high, but very small compared with the cost of damages which might have been assessed against the responsible doctor by a jury if the repair had not been made

In cases which cannot be disposed of in this manner, it is customary to hold a medical review or trial in the general locality of the defendant's practice. A jury of six or eight doctors in the area is selected to hear the case and the medical defense committee sits as judges Every aspect of both sides of the case is fully discussed in the presence of the plaintiff and his attorney if they care to attend At the close of the case, the jury determines whether or not the defendant doctor was guilty of malpractice, error, or mistake, and whether the case should be settled or resisted in court The finding of the jury is accepted by the Association and the insurance company, and the case is then handled in accordance with the findings

The Association attaches great importance to this procedure because of the educational and sobering effect it has upon the defendant and members of the jury, some of whom have occasionally been put on the jury because they, themselves, are believed to be potential offenders

Applicants for membership in the Los Angeles County Association are required, before admittance, to attend three indoctrination or orientation lectures, one of which is on the subject of malpractice liability

Every member who applies for insurance is required to have a thorough inspection of his office, equipment, routine records, nurses, technicians, etc , before his application is approved The inspection is made by experts trained by the Association, which fixes the minimum standards of acceptability Insurance is not granted to a member if the Association fails to approve his application Applicants are required to pay a $5 00 fee for the inspection, whether their applications are approved or not

It is reported that approximately 240 malpractice claims arise each year against the 3,500 members insured in the Association's insurance plan Of these, 70 per cent, or about 170, result in suits filed Of the suits filed, 30 per cent, or approximately 20 a year, result in payments of some kind to the plaintiffs Some judgments have been obtained, but all of them have been appealed and reversed or compromised before the appeals were heard. This is the basis for the statement that there have been no judgments in eight years against members insured in the Association plan Of all the cases filed in Los Angeles County, 54 per cent are against doctors whose professional standing is rated in the community as better than average Eight cases have been against teachers in local medical schools

It was further reported that the number and cost of malpractice actions against members insured in the Association's plan have slowly decreased since 1946, but those against others have remained about level or are increasing

Apparently the discipline and solidarity of purpose among the members of Los Angeles County is not as

cases where authorization is made to a veteran to receive care under this home town fee basis system, that the veteran have full opportunity for his free choice of physician, including specialists There have been some efforts in various local areas on the part of the Veterans Administration physicians to interfere with this free choice prerogative A few months ago in the New York City area it was found that the Veterans Administration clinic facilities were not able to accommodate patients within a two-week period This was then called a hardship case and the recommended medical care was to be provided by a private physician The directive contained the following sentence "Under this hardship category the veterans will not have the privilege of selecting the physician who is to render the treatment required." We made immediate and vigorous objection to this policy and I am happy to say that the director of the Out-Patient Service, Washington, D C , and the medical director of the New York State Branch promptly changed this directive, which after all was mainly the idea of a local branch subordinate

It is my belief that the Veterans Administration with its experience in this Plan subscribes to the superiority of the free choice principle It should be pointed out that authorization for medical care is possible only to service-connected cases The authorization is granted only when Veterans Administration facilities are not feasibly at hand, resulting in the "hardship" status for the veteran The building up of clinical facilities by the addition of part-time personnel constantly reduces the number of fee basis patients It is in my opinion most unfortunate when such physicians, who should be treating these patients privately under a fee basis plan, are treating patients in overcrowded clinics It is curious that some of these physicians, who are thus working at substandard rates, complain that their home town fee schedule is too low or that they are losing their private patients to Veterans Administration outpatient departments The contract with the Veterans Administration provides a fee schedule which is an independent one for New York State The format is that quite universally used in all of the states, but the fees are a matter of special agreement between the Veterans Medical Service Plan of New York, Inc , and the Veterans Administration

At the first of the year we encountered a great difficulty in that the general accounting office (Bureau of the Budget, Washington, D C) challenged the validity of Part II of the agreement between the Veterans Administration and the Veterans Medical Service Plan of New York, Inc Inasmuch as the general accounting office holds a supervisory relationship over the financial activities of other Federal agencies, the branch medical director was forced to suspend all other authorizations and payments based on the fee schedule set forth in Part II and to substitute the fee scale set forth in the so-called Veterans Administration National Fee Schedule To give some idea as to the subjugation of medical care in these instances I quote from the letter of the Branch Medical Director "Neither you, nor I, nor anyone in the Veterans Administration in Washington has any option in this matter We must follow the general accounting office's mandate "

Part II was challenged because "it was a tentative agreement and not a firm agreement supported by the firm acceptance of all contracting parties" However, we had been operating under this Part II system from September, 1946, to January, 1949 I am pleased to report that after a few prompt meetings with the Veterans Administration officials we were able to agree upon a new fee schedule which was officially accepted as of April 1, 1949 This schedule was adopted by the Plan after it was thoroughly reviewed by the Liaison Committee. All of the fee schedule material had been studied and approved by the Liaison Committee, representing the Medical Society of the State of New York, before it was adopted by the Plan We have also endeavored to keep our fee schedule in all respects equal to that of our Workmen's Compensation Fee Schedule I believe that our fee schedule is sufficiently high to merit the good professional services which we demand and that it is also very considerate of the cost to the Federal government These fee schedules are subject to revision and agreement from time to time and we are glad to take up any item which the Veterans Administration or the participating physician may complain of as unjust I wish to emphasize that this is a joint fee schedule and it represents the mutual satisfaction of the Veterans Medical Service Plan of New York, Inc , and the Veterans Administration The new fee schedule is known as Fee Catalog No 4.

The House of Delegates in 1948 adopted a resolution asking that representatives from the Medical Society of the State of New York meet with representatives of various veteran groups This meeting was held as a dinner meeting at the Hotel Commodore on February 9, 1949 It was attended by the President of the Medical Society, the Board of Directors of Veterans Medical Service Plan of New York, Inc , and the Liaison Committee of the Medical Society The veteran groups were represented by the American Legion, the Disabled American Veterans, the American Red Cross, and the Catholic War Veterans Other veterans' organizations were invited There was a thorough discussion of the medical, surgical and hospital services for veterans, especially those veterans with service-connected disabilities who were eligible for care under the Plan A much better understanding of our purposes resulted from this meeting Several veterans expressed the view that the medical profession might take a greater interest in their claim and pension examinations This especially referred to reports made by physicians following these examinations It was pointed out that all of this work is done by physicians who are employes or direct designates of the Veterans Administration and that this portion of the service was not included in the operation of our Plan. There was general expression that the veterans should have free choice of physician, but many of the veterans thought that there should be no curtailment of clinic facilities or veterans hospitals It was decided to hold similar meetings from time to time It appeared that the veterans in attendance at the meeting were impressed with the fact that the Medical Society of the State of New York is interested in securing the best medical care for veteran patients

Statistics offer some difficulty in determination, but it may be of interest to report some figures During the fiscal year which ended June 30, 1948, 98,609 veterans were treated by private physicians under the Veterans Medical Service Plan of New York Inc , at a cost of $2,582,761 to the Veterans Administration About 59 per cent of all VA outpatient medical care in the State was performed by non-VA physicians Under a similar arrangement with dentists 95 per cent of all dental care rendered during the year was performed by non-VA dentists, 94,238 treatments and 64,279 examinations were authorized to fee basis dentists and were completed at a cost of $7,688,016 to the Veterans Administra-

Supplementary Report of the Council—Part VII Medical Care Insurance

To the House of Delegates, Gentlemen

The Council Committee on Economics submits the following Supplementary Report

At a meeting of the Subcommittee on Medical Expense Insurance, held at the Society offices February 25, jointly with the presidents of the six State Society approved medical care insurance plans, or their representatives, the feasibility of establishing a State-wide contract with uniform benefits, to be offered by present plans but not to supersede present contracts, was discussed

For the information of the Committee, Mr Farrell read a statement outlining differences in present contract provisions in the plans, and also called attention to selected items on a comparative fee schedule to illustrate the lack of conformity in fees throughout the State

All aspects of this program were discussed at length and resulted in the following recommendations

That a State-wide uniform contract be established, that it offer surgical, in-hospital medical benefits, including fractures and maternity, that surgical care be rendered in the hospital, home, or physician's office, and that medical care be confined to in-hospital cases,

That the contract embrace service and indemnity features, the point of distinction being income limits, that the tentative income ceiling be $5,000 for a family of two or more

After further discussion, consideration was given to ceilings of $2,500 for an individual, and $4,000 to $4,500 for a family of two or more The voting on this was not unanimous, but all ceilings considered were tentatively recommended and not regarded as final.

A provision in present contracts governing the age limit of sixty-five or over, in relation to enrolment and continuous coverage after age sixty-five, was referred back to each plan with a recommendation that serious consideration be given to possible increases in claims from this group, and that studies be made of these groups before plans are committed to a policy, that once a subscriber he may remain so regardless of age

The distinction exercised by some plans in the payment of fees to participating and nonparticipating doctors in plan operating areas was discussed, and it was recommended that this matter be left to the judgment of local plans and that the Medical Society of the State of New York implement its component societies to be vigilant in urging nonparticipating physicians to affiliate with their local plan

It was recommended that the services of an actuary be obtained for this program and that plans be approached to share pro rata the expense entailed

Mr Farrell was authorized to contact each plan, to obtain information necessary to amplify a policy which would be acceptable State-wide, and to solicit the aid of committee members in this project

The actions of this Committee, as recommended, were presented to the Council at its March 10, 1949, meeting and were accepted in principle It was voted that the Council favors a contract according to the 1948 House of Delegates, and that the Committee proceed with the formulation of such a contract

Respectfully submitted,

CARLTON E. WERTZ, M D , *Chairman*
Council Committee on Economics

Section 11 (A) (See 82)

Annual Report of the Board of Directors of Veterans Medical Service Plan of New York, Inc., and Report of the Council Committee on Liaison with Veterans Administration—Part VIII

To the House of Delegates, Gentlemen

This report includes in its contents reference to the work of the Liaison Committee of the Medical Society of the State of New York with the Veterans Administration Since the work of both groups relates to veterans' care it may serve for better understanding and brevity to present this as a combined report The Veterans Medical Service Plan of New York, Inc , is an independent group set up so that contracts for veterans' medical and surgical care could be made by the Veterans Administration with the practicing medical profession of the State of New York.

The first contract was signed August 7, 1946, and began operating September 15, 1946 During this period there have been several extensions of the contract, and in the past year this has been done for three-month periods with little substantial change in the contract

Our present contract expires June 30, 1949, which is the end of the Federal fiscal year and the regular time for expiration of contracts

The contract includes, as it has from the beginning, employment of physician Coordinators by the Veterans Medical Service Plan of New York, Inc. The Veterans Administration furnishes a sum to the Veterans Medical Service Plan of New York, Inc., which is to enable the Plan to pay its Coordinators. The Coordinators are, however, wholly the employes of the Veterans Medical Service Plan of New York, Inc These Coordinators are the following physicians

George Hunter O'Kane, M D	New York City
Paul T Crosby, M D	Syracuse
Frederick H Petters, M D	Buffalo
Thomas G Fitzgerald, M D	Albany
A. W Rupert, M D	Albany

Briefly, the duties of Coordinators include integration of Veterans Administration activities with respect to physicians participating in the Veterans Medical Service Plan of New York, Inc , review, approval, and adjudication of all claims for payment for services rendered under the Plan, individual review and approval of the content and nature of the professional report submitted by the physician, and procedures concerning complaints registered against participating physicians, particularly with regard to question of ethics involved Although the Veterans Administration could make more use of the consulting capacities of our Coordinators, the system of review is in most respects ideal As of the quarter beginning April 1, 1949, there are no new complaints against doctors participating under the Plan which require investigation Minor difficulties or disagreements with physicians have been handled by telephone or letter with satisfactory final disposition

The Coordinators are physicians of high standing and are universally respected in all areas by veteran patients, the practicing physicians and their county societies, and by the Veterans Administration Later figures in this report will give some idea of the huge amount of professional work that has been transacted since the beginning of the Plan in September, 1946 Every complaint over any act has been investigated and properly taken care of, and the Medical Society of the State of New York may well be proud of the conduct of its physicians in this large and difficult venture We have insisted that in all

It may be noted that since the completion of the first part of this report the number of eligible children has increased from 62 to 65 and the total recorded number of former members of the Society who were killed in action, died of wounds or disease incurred in the service during World War II has increased from 32 to 34.

The total amount of the War Memorial Assessment as received to date of this report is $182,287 50 instead of the $139,096 as given in the first part of the report leaving an estimated balance of $59,-

tion In the comparison of figures in medical and dental care it should not escape notice that 95 per cent of the dental care was performed by private dentists

During the fiscal year about $50,000,000 was spent in New York State directly or indirectly in providing medical care for veterans The total expenditure by the Veterans Administration in New York State is reported to be about $600,000,000 for the fiscal year, exclusive of the cost of new hospital construction, which figures are not included in the Branch budget In a summary of its activities, (U S) as of August 31, 1948, the Veterans Administration reported a total of 105,048 patients in hospitals, 92,983 of these patients were in Veterans Hospitals and, of these, 61,091 were veterans with non-service-connected disabilities Of the 12,065 not in VA Hospitals, 7,488 were veterans with nonservice-connected disabilities In the metropolitan area of greater New York and adjacent counties, the number of authorizations for fee basis work for the year 1948 (January, 1948, through December, 1948) was 6,868 with fees of $217,280 This illustrates the marked reduction in free choice in the more populated areas and further illustrates that the veteran does not have the same opportunity for private care in various areas of the State

In the entire United States it is reported that private physicians treated 761,165 veterans during the fiscal year of 1948 under the Veterans Administration "home town medical care program" The physicians were paid $11,437,739 for the 2,735,429 treatments given In addition, Veterans Administration staff physicians at outpatient clinics handled 865,004 cases involving 1,680,183 treatments and visits

The reduction in private care under the Plan in New York State has not been so rapid in the latter half of the year However, I believe there is at least a 25 per cent reduction in treatment over that of the previous year in fee basis treatment It is my belief that this reduction will be more marked in the present fiscal year because we have recently had large new facilities put into operation in the larger cities of the State Although there are many physicians employed by the Veterans Administration, most of these have been busied with administrative duties, authorizations, claim and pension examinations This work is of necessity performed by the Veterans Administration employes However, as indicated earlier in this report, I see no good reason why most of the outpatient treatment should not be given by the private physician It would result in greater appreciation by the veteran and in a lower cost to the government, especially when overhead is considered

The number of veterans awaiting hospitalization in VA hospitals has been steadily increasing This is especially true in tuberculosis and neuropsychiatry, and for these cases the Veterans Administration may not be able to provide beds in their own hospitals for some time to come The increase in non-service cases awaiting hospitalization continues Although new Veterans Hospitals are under construction, the lack of personnel has made it difficult to take care of all the beds at present in operation It seems that soon the VA will have to call upon the local physician and the local private hospital for more help It would be well to change the policy so that more veterans would be taken care of in local community hospitals The project of medical and hospital care to the veteran is still a most portentious one

The chairman of the Liaison Committee, who is also the president of Veterans Medical Service Plan of New York, Inc , has made frequent reports to the Council of the Medical Society of the State of New York We have endeavored to follow faithfully the advice and wishes of the Council in the knowledge that we are thus carrying out the wishes of the Medical Society membership

The members of the Liaison Committee are
